

# HOW TO MASTER ORDERFLOW

***Welcome to this guide.***

***Inside, you will learn how to use four of the most powerful tools available to traders: the Order Book, Volume Profile, Liquidation Heatmap, and Market Profile. These are not random indicators you throw on a chart. They are professional tools designed to help you understand what is really happening behind price movement.***

***Each section will explain the tool step by step, show you how to interpret it, and outline what bullish and bearish setups look like. At the end, you will see how to combine these tools together for even more clarity.***

***As with anything in trading, practice matters more than theory. Use these concepts, but also test them, study live markets, and apply your own edge. The more you put in, the more you will get out.***

***Let's begin.***

*Soulz*

## How to Access the Indicators:

1. Open your browser and go to <https://kiyotaka.ai/ref=4mS0bx7xQg>

2. Click **Get Started** or **Log In**

3. After signing in you will land on the charts. Do the platform tour to get familiar with the layout and tools.

4. Remove any default indicators by clicking the **X** on the upper-left of the indicator panel.

5. Once removed, open the **Indicators** menu.

6. Switch to the **Community** tab

7. Type **SCF** in the search bar. Our indicators should appear. Make sure the author listed is **@SoulzBTC** before adding.

8. Add the indicators you need, then save your chart layout if you plan to reuse it.

# 1. ORDER BOOK

The order book is one of the most fundamental tools in trading. It records all the buy and sell orders that traders place at different price levels. By reading the order book, you can see where market participants are willing to buy, where they want to sell, and how much volume is waiting at each level.

It is not just a list of numbers. It is a real-time snapshot of supply and demand that reveals liquidity, market sentiment, and potential turning points.

## What is an order book?

An order book for any asset, whether it is Bitcoin, Ethereum, or a stock, displays all outstanding limit **orders**. The **bid side** shows the buyers and the prices they are willing to pay. The **ask side** shows the sellers and the prices they want to receive.

## Order book

| Order                                                                                   | Volume | Buy   | Sell  | Volume | Order |
|-----------------------------------------------------------------------------------------|--------|-------|-------|--------|-------|
| 2                                                                                       | 1452   | 2,842 | 2,850 | 647    | 2     |
| 4                                                                                       | 2635   | 2,840 | 2,852 | 1179   | 1     |
| 2                                                                                       | 2756   | 2,838 | 2,854 | 2656   | 4     |
| 3                                                                                       | 3621   | 2,836 | 2,856 | 3009   | 2     |
| 2                                                                                       | 979    | 2,834 | 2,858 | 829    | 3     |
| 3                                                                                       | 8566   | 2,832 | 2,860 | 5000   | 1     |
| 4                                                                                       | 6382   | 2,830 | 2,862 | 13587  | 3     |
| 2                                                                                       | 958    | 2,828 | 2,864 | 804    | 2     |
| 2                                                                                       | 3596   | 2,826 | 2,866 | 5000   | 1     |
| 5                                                                                       | 22030  | 2,824 | 2,868 | 2714   | 2     |
| <div> <div>29</div> <div>52975</div> <div>^</div> <div>35425</div> <div>21</div> </div> |        |       |       |        |       |

Key terms to remember:

- **Bid:** The highest price a buyer is willing to pay.
- **Ask:** The lowest price a seller is willing to accept.
- **Spread:** The difference between the best bid and the best ask.
- **Order wall:** A large cluster of buy or sell orders at a specific price.
- **Liquidity gap:** A price zone with few orders, where price can move quickly.

## How the order book works

When a new buy limit order is placed, it gets added to the bid side. When a sell limit order is placed, it goes to the ask side. Orders are arranged by price and time priority.

- On the **bid side**, the highest bids appear at the top.
- On the **ask side**, the lowest asks appear at the top.

Whenever a market order is placed, it executes against the best available order on the opposite side. After that trade, the order book updates instantly to reflect the new balance of buyers and sellers.

## What traders should look for

The order book reveals three main characteristics of a market:

### Market Spread

- Difference between best bid and best ask
- Narrow spread = high liquidity
- Wide spread = low liquidity

### Market Depth

- Amount of buy and sell orders at each level
- Deep book = strong liquidity
- Shallow book = volatile price moves

### Market Balance

- More bids stacked = stronger demand
- More asks stacked = stronger supply
- Maker walls act as magnets, but outcome depends on supply vs demand

## When is it bullish?

What to look for:

- Large buy walls sitting under price attract taker buys and provide support
- Weak sell walls above price that get absorbed quickly
- Buyers stepping in repeatedly at the same level, reducing downside follow-through

## When is it bearish?

What to look for:

- Large sell walls sitting above price that absorb taker buys and act as resistance
- Bid liquidity thinning out under price while sellers continue hitting the bid
- Sellers stepping in heavily at range highs or after rejection wicks

## Live Example

### Bullish:

This is just a simple example, but it shows how to read the order book in real time. Look at the highlighted box in the screenshot. Notice the large quantity stacked at those prices. If price dips into that level, there is a high chance it will hold instead of breaking lower. Of course, this always depends on the situation, but it demonstrates how order book liquidity can act as support.

## Bearish:

Now for the bearish example. This is also a simple case to illustrate how the order book can signal resistance. In the screenshot, look at the highlighted box. There is a large quantity stacked at that price level. When price pushes into that area, it will likely react and struggle to move higher. This is the mirror image of the bullish scenario, where instead of support holding price up, heavy sell orders create a ceiling.

## Trading takeaway

The Order Book is best used for short term insights. It shows real-time sentiment and liquidity but can change in seconds as traders add or cancel orders. Use it to confirm setups, identify where liquidity is sitting, and avoid trading blindly into heavy walls.

It is not a standalone strategy, but when combined with volume tools and price action it becomes one of the clearest ways to read the market's intentions.

## 1.1 THE SCF ORDERBOOK INDICATOR

The SCF Order Book Imbalance Indicator is a custom tool we built on top of the traditional order book. While the normal order book shows raw bid and ask levels, this indicator reveals real-time buying and selling pressure in a way that is easier to read.

Green bars mean buyers are in control. Red bars mean sellers are in control. By analyzing order flow directly, the indicator shows you what institutional traders and smart money are doing right now, not what they did in the past.

### Key Features

- Real-time market sentiment
- Institutional order flow visibility
- Immediate pressure detection
- Customizable depth analysis
- Perfect for high-frequency trading

## Why this matters

Traditional order books can feel noisy or overwhelming. Our indicator simplifies it into a clear visual. You see at a glance whether buyers or sellers are dominating, and how aggressive the pressure is.

This is especially powerful for scalpers and intraday traders who need to make fast decisions. Instead of interpreting thousands of lines of bid and ask data, you get a live pulse of the market's intention.

## How to use it

- **Bullish signal:** Strong and consistent green bars, often paired with price holding key support.
- **Bearish signal:** Dominant red bars, especially during breakdowns or failed bounces.
- **Neutral signal:** Choppy flips between green and red, usually during low-volume consolidation.

This indicator is not meant to replace the traditional order book, but to enhance it.

## 2. VOLUME PROFILE

Volume Profile shows where the most trading activity occurred at each price level. Instead of looking at volume by time, it looks at volume by price. This gives you a map of where traders consider fair value and where the market rejects price.

### Key concepts

- **Point of Control (POC):** The single price level with the highest traded volume.
- **High Volume Node (HVN):** An area of heavy trading activity that acts as strong support or resistance.
- **Low Volume Node (LVN):** A thin area with little trading activity where price tends to move quickly through.
- **Value Area:** The price range that contains about 70 percent of volume traded.

## When is it bullish?

What to look for:

- Price bouncing off the POC and holding above.
- Rejection of LVNs to the downside followed by strong recovery.

## When is it bearish?

What to look for:

- Price failing to hold above POC and falling back into lower levels.
- Rejection at value area high.
- Movement through an LVN to the downside without resistance.

## **Trading takeaway**

Volume Profile helps traders identify levels that actually matter. Traditional support and resistance can be vague, but when tied to heavy volume it gains more weight. Think of HVNs as magnets and LVNs as open space.

## **Volume Profile vs. Footprints**

Volume Profile maps out where trading activity took place by showing the total volume at each price level. It highlights areas such as the Point of Control, high volume nodes, and low volume nodes, which often act as support or resistance. This makes it a great tool for identifying value zones and understanding where the market has accepted or rejected price.

Footprint charts go one layer deeper by showing how that volume was executed inside each candle. They break down trades into buys hitting the ask and sells hitting the bid, revealing which side was more aggressive at a given level. In short, Volume Profile shows where the market was active, while Footprints show who had control at those prices.

### 3. LIQUIDATION HEATMAP

The liquidation heatmap tracks where traders who use leverage will be forced to close positions. These zones act like magnets because once price gets close, the cascade of liquidations can accelerate the move.

#### How to interpret the heatmap

- **Bright clusters:** Areas with a high concentration of liquidations.
- **Long liquidation zones:** Below price, showing where overleveraged longs could get closed.
- **Short liquidation zones:** Above price, showing where overleveraged shorts could get squeezed.

## When is it bullish?

What to look for:

- Large cluster of short liquidations above current price.
- Price grinding upward toward those clusters.
- Squeezes triggering rapid moves above as shorts get forced out.

## When is it bearish?

What to look for:

- Heavy clusters of long liquidations stacked below price.
- Market drifting lower with weak bounces.
- Big red candles as longs are wiped out.

## Trading Takeaway

The liquidation heatmap is ultimately about identifying trader pain. Most retail traders misuse leverage, placing positions too close to obvious levels, and end up getting liquidated in clusters. These areas act like magnets because the market often seeks out liquidity to fuel the next move.

By tracking where liquidations are stacked, you gain insight into potential targets. A cluster of short liquidations above price can trigger a squeeze when buyers force shorts to cover, driving price higher. A cluster of long liquidations below price can create a cascade as longs get forced out, accelerating a selloff.

This tool should not be used in isolation, but when paired with order flow or volume analysis it can help explain why price moves so sharply at certain levels.

Understanding where traders are most vulnerable allows you to anticipate where the next expansion might occur and prepare to trade with the flow, rather than against it.

## 4. MARKET PROFILE

Market Profile is similar to Volume Profile but it organizes data by time and price distribution. It shows where the market spends time and helps define value. It is widely used in futures trading for understanding auction theory.

## Key concepts

- **Initial Balance (IB):** The first hour of trading in futures markets. Often sets the tone for the session.

- **Value Area (VA):** Where most trading took place during a session.

- **Point of Control (POC):** The level where the most time was spent.

## **When is it bullish?**

What to look for:

- Price accepting above the value area high.
- Trend days where price never returns to the value area.
- POC shifting upward across sessions.

## **When is it bearish?**

What to look for:

- Price failing to hold value area high and dropping back inside.
- Acceptance below the value area low.
- POC shifting lower across sessions

## Live Examples

**Example #1:** In this example, price first moved up from point A and then built balance at point B, forming a sideways consolidation zone. At point 2, sellers rejected the highs and pushed price lower.

This is a classic Market Profile setup: rejection at the extremes, followed by a response at the value edge. Traders often look for these rejection signals to fade moves that fail to gain acceptance outside of value.

**Example #2:** Here, price dipped into a low volume node (highlighted by the black box), where strong buyers stepped in and reversed the move almost immediately.

This shows rejection of lower prices in an area where the market previously showed little acceptance. It is a textbook example of a Market Profile response off a low volume zone, offering a high-probability reversal setup.

## Trading takeaway

Market Profile gives structure to the day. It helps intraday traders understand whether the market is trending, balancing, or rejecting levels. Combined with Volume Profile it gives one of the clearest pictures of where value lies.

## Volume Profile vs Footprints vs Market Profile

Although these three tools are often grouped together, each one serves a different purpose. Understanding how they differ helps you choose the right tool for the right scenario.

**Volume Profile** shows how much volume traded at each price level over a session or selected range. It highlights areas like the Point of Control, high volume nodes, and low volume nodes. This makes it best for spotting support and resistance zones based on actual traded volume.

**Footprint Charts** go deeper by displaying how that volume was executed inside each candle. They separate aggressive buys (hitting the ask) from aggressive sells (hitting the bid) to show which side was in control at specific prices. Footprints are ideal for order flow analysis, absorption studies, and identifying imbalances during fast-moving markets.

**Market Profile** focuses on time rather than raw volume. By plotting Time Price Opportunities (TPOs), it shows where price spent the most time, which levels were accepted as value, and which were rejected quickly. Traders often use it to gauge whether a session is trending or balanced, with concepts like Initi

## 5. COMBINING IT ALL TOGETHER

No single tool is enough to trade with confidence. Each one shows a different part of the market, and the real edge comes from combining them. By layering these perspectives, you filter out noise and increase the probability that your trade idea is backed by real conviction.

It is also important to note that examples using tools like the SCF Order Book Indicator, Volume Profile, Liquidation Heatmap, and Market Profile are very different from traditional technical analysis. Classic TA relies heavily on chart patterns, moving averages, or oscillators that lag behind price. These tools, on the other hand, are built around **real-time order flow, liquidity, and market structure**. They show you what traders are doing right now, where value is forming, and where pain points exist. This forward-looking perspective helps you anticipate moves instead of simply reacting to them.

### a. SCF Order Book Indicator + Liquidation Heatmap

This combo highlights where real-time pressure and trader pain overlap. If the SCF Order Book Indicator shows dominant green bars (buyers in control) while the Heatmap reveals a cluster of short liquidations above, the stage is set for a squeeze. On the other hand, if red bars dominate (sellers in control) while long liquidations pile up below, it signals the potential for a cascade lower.

Example:

### b. SCF Order Book Indicator + Volume Profile

This combination connects what is happening live in the order flow with the bigger picture of where volume has built up over time. The SCF Order Book Indicator shows immediate buying or selling pressure, while Volume Profile highlights high and low volume zones that often act as magnets or rejection points.

For example, if green bars dominate while price is breaking out above a High Volume Node, it signals strong continuation potential. If red bars dominate while price approaches a Low Volume Node, it suggests sellers may drive price through thin liquidity.

Example:

### c. Market Structure + Volume Profile

This combo pairs overall context with key levels. Market structure shows whether price is trending or balancing, while Volume Profile highlights where trading activity was concentrated.

For example, a higher low forming at a High Volume Node signals strong support. A lower high rejection at a Value Area High signals continuation lower. Together, they give both direction and conviction.

## 6. SUMMARY OF TOOLS

Each tool in this guide has its own strength. Knowing what each is best at helps you decide which one to lean on in different situations.

- **SCF Order Book Imbalance Indicator**  
Best for spotting real-time buying and selling pressure. Works well for scalping and short-term confirmation of liquidity shifts.
- **Volume Profile**  
Best for identifying support and resistance based on traded volume. Highlights value zones, High Volume Nodes, and Low Volume Nodes that act as magnets or rejection areas.
- **Liquidation Heatmap**  
Best for locating trader pain points. Reveals clusters of long or short liquidations that often act as price targets during squeezes or cascades.
- **Market Profile**  
Best for understanding session structure. Shows where price spent the most time, helping traders distinguish between trending and balanced days.

Together, these tools give a full picture: pressure in real time, historical levels of interest, vulnerable positions, and market context.

## Closing Notes

These tools are professional grade. They take time and practice to master. At first they may seem overwhelming, but as you study them daily you will start to see patterns repeat.

Do not rely on any one signal. Trading is about stacking probabilities. Use these tools to filter out noise, avoid weak setups, and trade with higher conviction.

The market is always uncertain, but with the right tools you can navigate it with more confidence.

Now it's your turn. Apply these tools, test them on live charts, and sharpen your edge.
