HOW TO MASTER THE ART OF TRADING

2025

Welcome to this advanced guide.

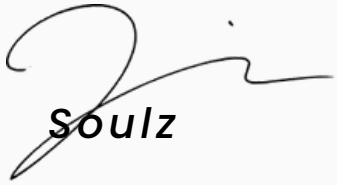

Inside, you'll explore liquidity zones, structural pivots, advanced price action setups, and the deeper layers of market structure.

This is more than just theory. It's built from experience, tested through real trades, and written to give you a true edge.

I'm glad you're here. Your time, focus, and curiosity mean a lot. I hope what's ahead challenges you, teaches you, and helps you level up.

Let's get started.

Sincerely,

Soulz

THE TRADER'S FOUNDATION

i. WHAT IS CRYPTO TRADING?

Crypto trading is the act of buying and selling digital assets such as Bitcoin, Ethereum, and other altcoins to profit from price fluctuations. It takes place on online platforms that operate around the clock, unlike traditional stock markets. The goal is to capitalize on market volatility using a variety of strategies.

Traders can engage in:

- Spot trading (buying and selling assets directly)
- Futures and derivatives (speculating on price direction without owning the asset)
- Scalping, day trading, swing trading, or long-term investing

Success in crypto trading requires technical skills, proper risk management, and strong decision-making.

ii. UNDERSTANDING EXCHANGES & MARKET STRUCTURE

A crypto exchange is where traders buy and sell coins. These exchanges come in two types:

- Centralized exchanges (CEX) like Binance and Coinbase, which manage orders and hold your funds
- Decentralized exchanges (DEX) like Uniswap and dYdX, which allow peer-to-peer trading from wallets

Understanding market structure helps traders read charts and recognize patterns. Price typically moves in trends, ranges, and breaks through key levels like support, resistance, and liquidity zones.

A few essential market structure concepts:

- Higher highs and higher lows indicate an uptrend
- Lower highs and lower lows suggest a downtrend
- Consolidation zones show indecision
- Breakouts reveal momentum shifts

Reading market structure lets traders anticipate moves before they happen.

ii. THE MINDSET OF A SUCCESSFUL TRADER

Having the right mindset is just as important as having a good strategy. Your emotions can be your biggest enemy if you let them guide your trades. Discipline, patience, and self-control are non-negotiable traits.

Here are key principles every trader should remember:

- Stick to a plan
  - Always trade with a strategy and predefined rules for entry, stop loss, and take profit.
- Control risk
  - Use position sizing and risk only what you can afford to lose. Never overleverage.
- Detach from emotions
  - Do not chase losses. Losing trades happen and are part of the process.
- Stay consistent
  - One winning day means nothing. Build habits that lead to long-term success.
- Keep learning
  - Markets evolve, and so should you. Stay updated, review your trades, and improve your edge.
- Track performance
  - Keep a journal of every trade. This helps you spot patterns in both your wins and your mistakes.

A successful trader is not just skilled. They are calm, calculated, and prepared for anything the market throws at them.

MASTERING PRICE ACTION TRADING

I. WHAT IS PRICE ACTION?

Price Action refers to the natural movement of price on a chart, without the use of lagging indicators. It focuses on reading candlesticks, chart patterns, and key levels like support, resistance, and trendlines to understand how the market behaves in real time.

Traders who use price action study how buyers and sellers interact, analyzing things like market structure, momentum, and liquidity zones to anticipate future moves. It helps identify potential entry and exit points by observing how price reacts at important areas, such as previous highs, lows, or zones of consolidation.

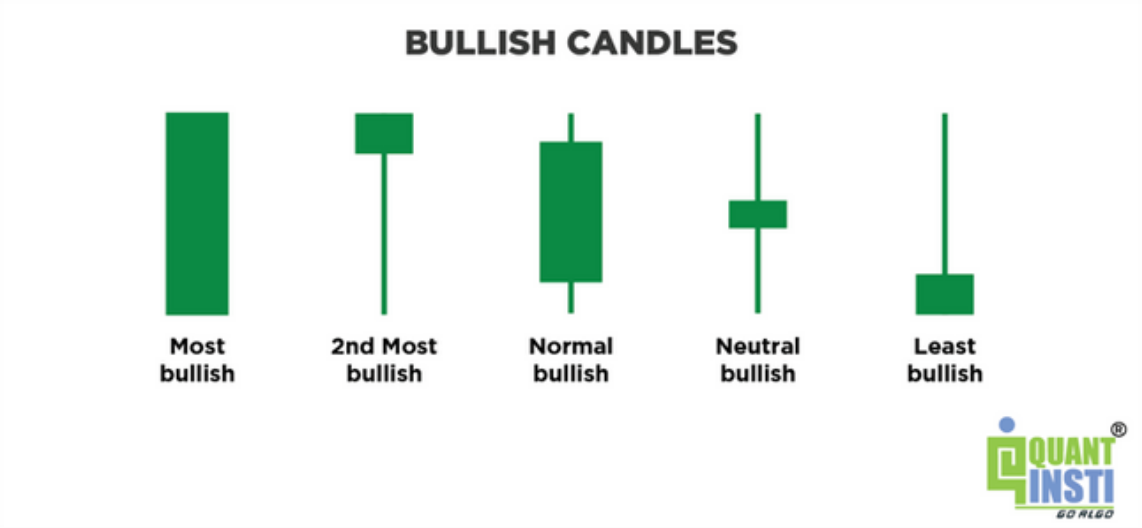

Price action trading relies heavily on clean charts, patience, and a deep understanding of market psychology. It is widely used because it adapts to all timeframes and works across different market conditions.

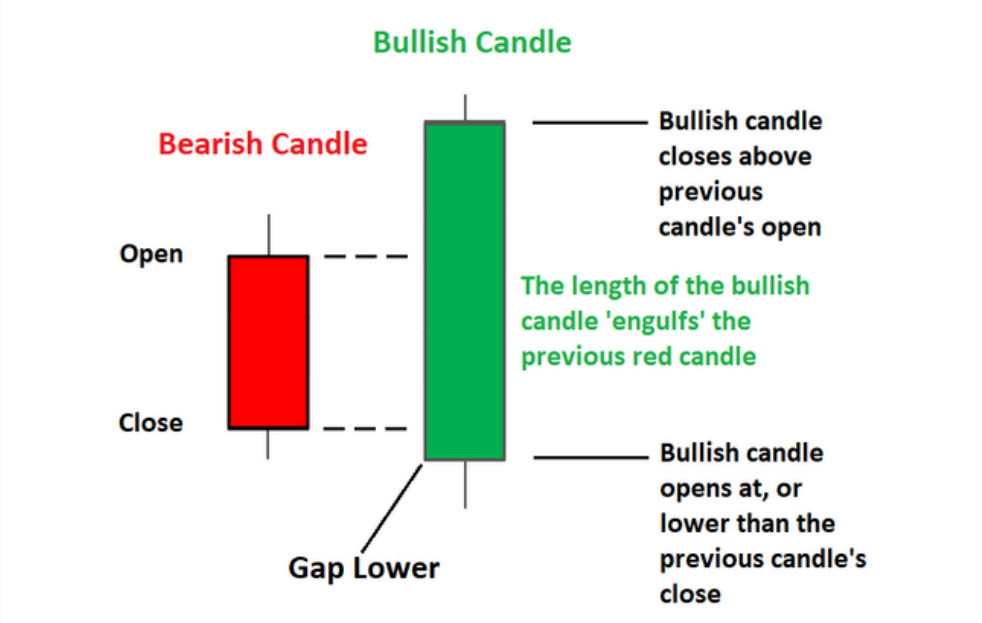

II. CANDLESTICKS: BULLISH CANDLE

A bullish candlestick pattern is a formation on a price chart that signals a potential uptrend or the continuation of an existing upward move. These patterns suggest that buyers are gaining control and that price may rise in the near future.

Each candlestick shows four key data points within a specific time frame: the opening price, closing price, highest price, and lowest price. Bullish patterns often appear at the end of a downtrend or during a pullback in an uptrend, giving traders clues for possible reversal or continuation setups.

Common bullish candlestick patterns include the bullish engulfing, hammer, and morning star, all of which reflect strong buying pressure in the market.

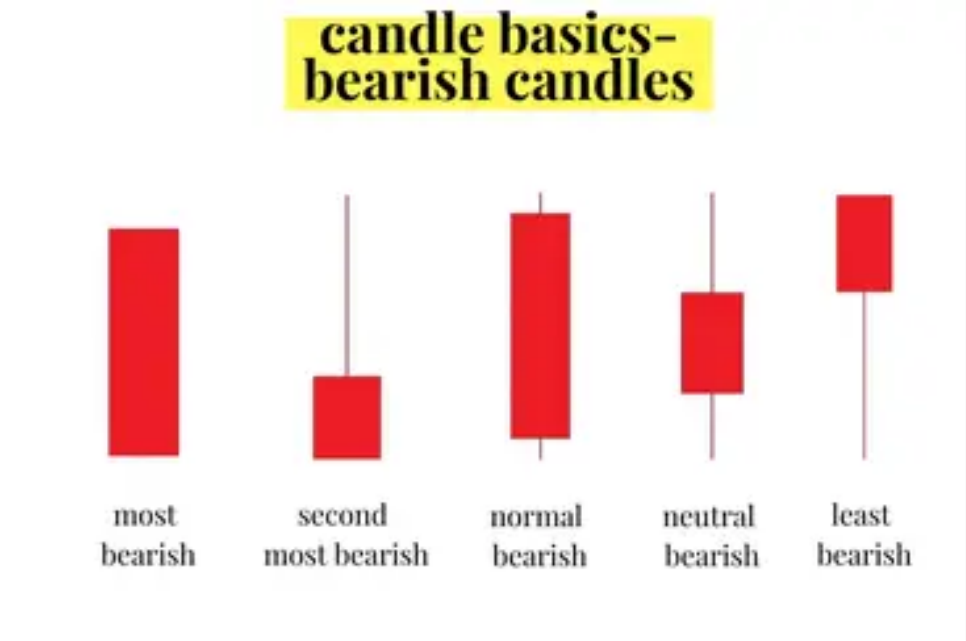

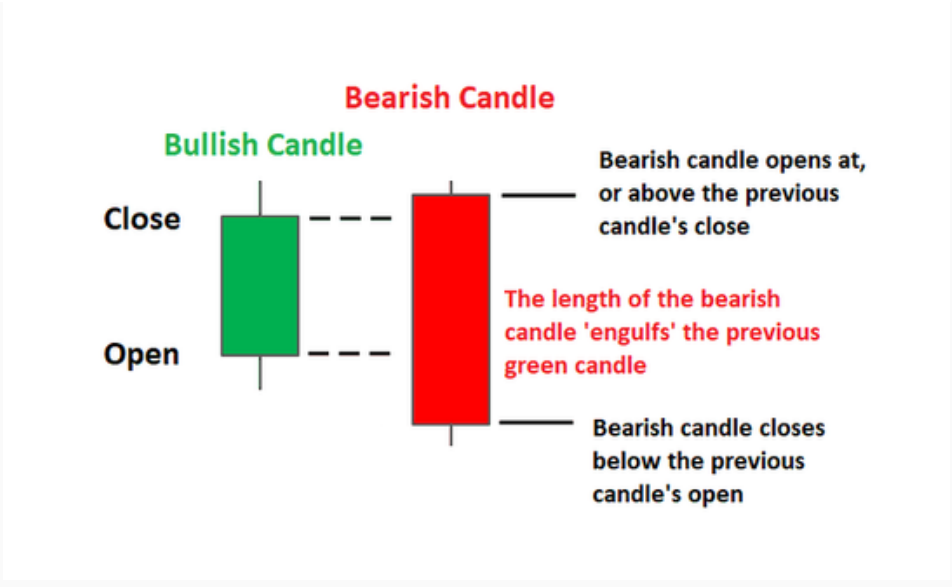

CANDLESTICKS: BEARISH CANDLE

A bearish candlestick is a visual indicator on a price chart that signals a potential downtrend or upcoming decline in price. It reflects selling pressure and a shift in momentum from buyers to sellers.

This candlestick is formed using four key values: the opening price, closing price, high, and low within a given time frame. In most charting platforms, a bearish candle typically appears red or black, showing that the closing price is lower than the opening price.

Bearish candlestick patterns often appear at market tops or after a retracement during a downtrend, helping traders spot potential reversal or continuation setups.

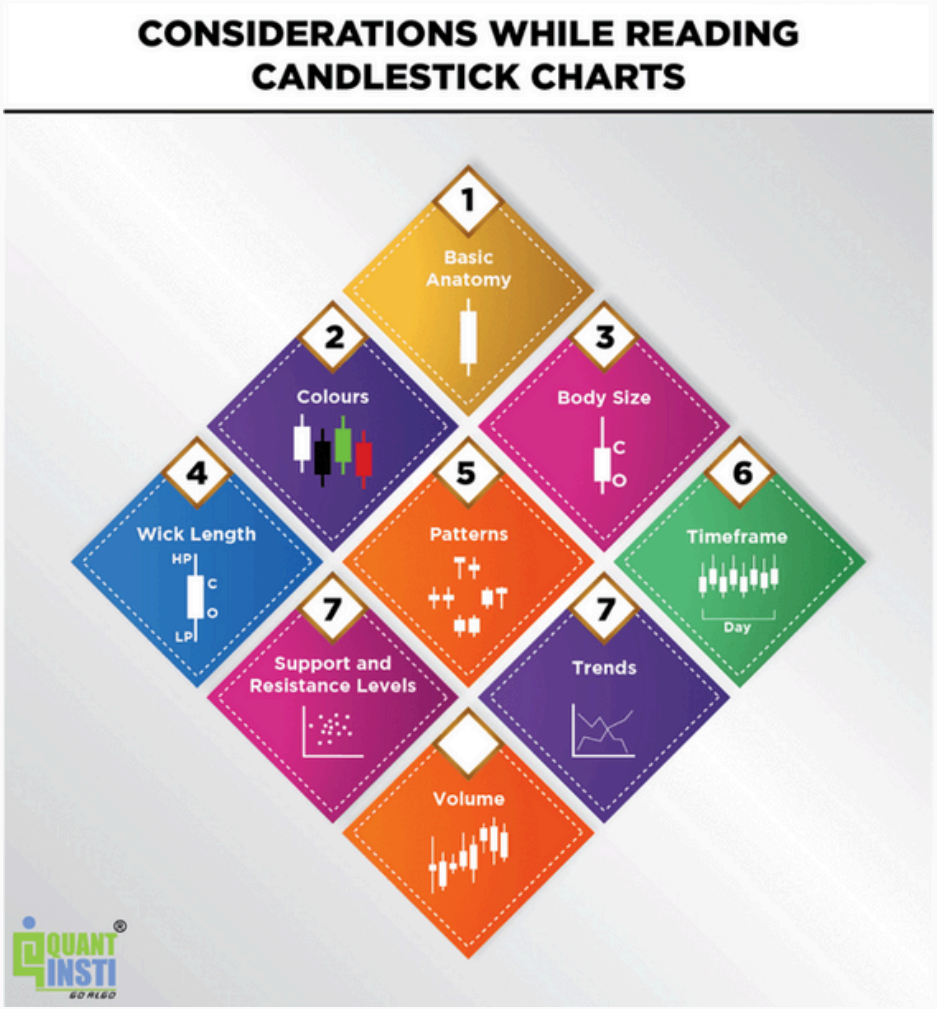

CANDLESTICKS: HOW TO READ?

These are the most important factors I consider before taking a position:

- Price Action (PA) of the coin
- Size of the candle bodies, which shows momentum and strength
- Recognizable patterns like breakouts, rejections, or consolidations
- The timeframe I'm trading on and how it aligns with higher or lower timeframes

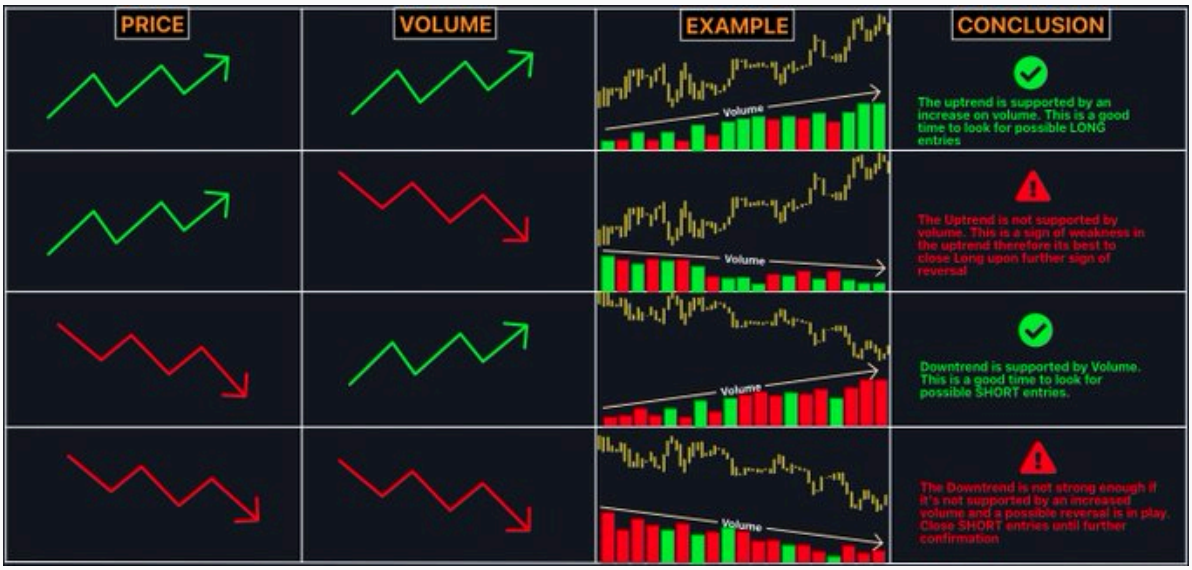

III. VOLUME

Volume represents the number of trades or contracts exchanged during a given period. A rise in volume often signals increased interest and conviction, which can lead to sharp price movements in either direction.

When volume is low, assets tend to be more volatile and less predictable. This is because lower liquidity means fewer participants, so even small orders can cause larger price swings.

Traders monitor volume to confirm trends, spot potential reversals, and filter out fake breakouts.

VOLUME

When volume declines while prices rise, it often signals that the uptrend is losing strength, increasing the chances of a reversal.

On the other hand, rising prices with increasing volume confirm strong bullish momentum and a healthy uptrend.

If prices are falling while volume increases, it suggests strong selling pressure and the likelihood of a continued downtrend.

VOLUME

When volume is decreasing while price is also falling, it typically indicates a bearish trend with weakening momentum.

However, if volume stops decreasing and stabilizes while price continues to fall, it can signal a long-term bearish outlook, suggesting that sellers remain in control and demand is not returning.

VOLUME

Tokens with high liquidity often show higher trading volumes, meaning they can be bought or sold quickly and with minimal price slippage.

Volume and liquidity are closely linked, both reflecting how active and efficient a market is.

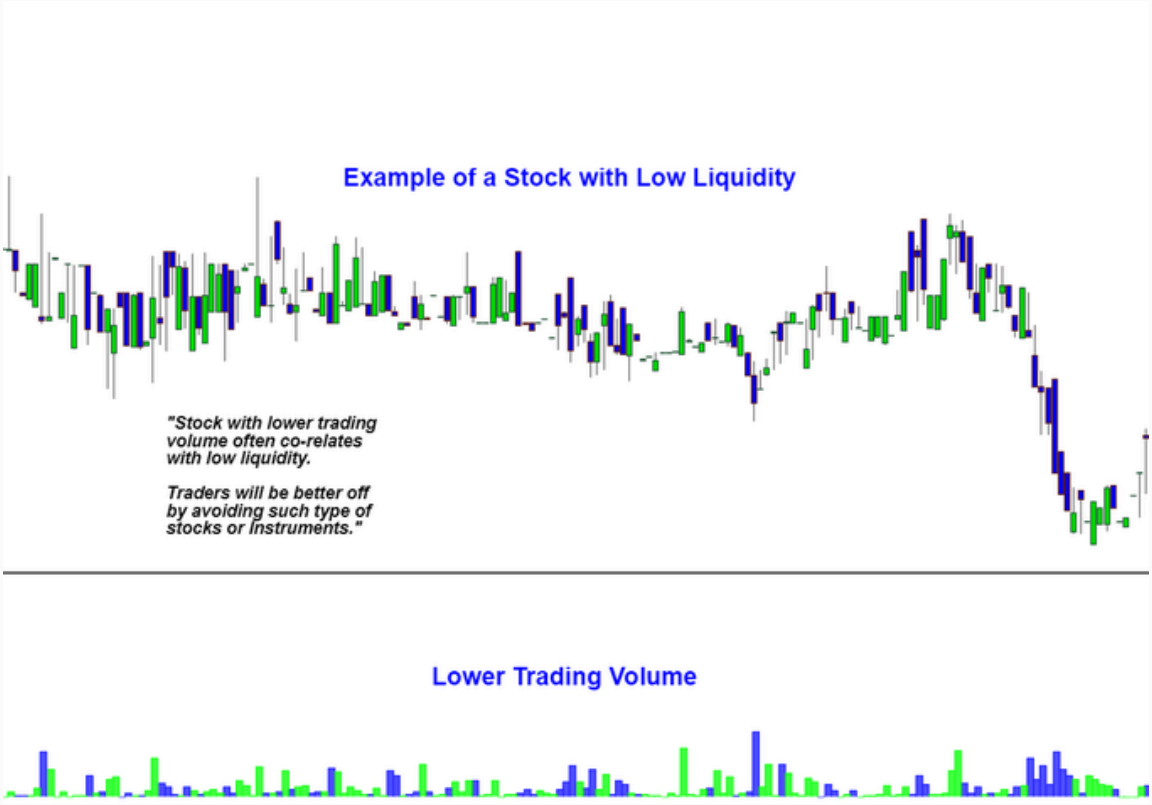

Tokens with higher volume are typically more attractive to traders, as they allow for faster execution and tighter spreads, making them more reliable for both short-term and long-term strategies.

VOLUME

When a token has low liquidity, it becomes vulnerable to sudden price swings.

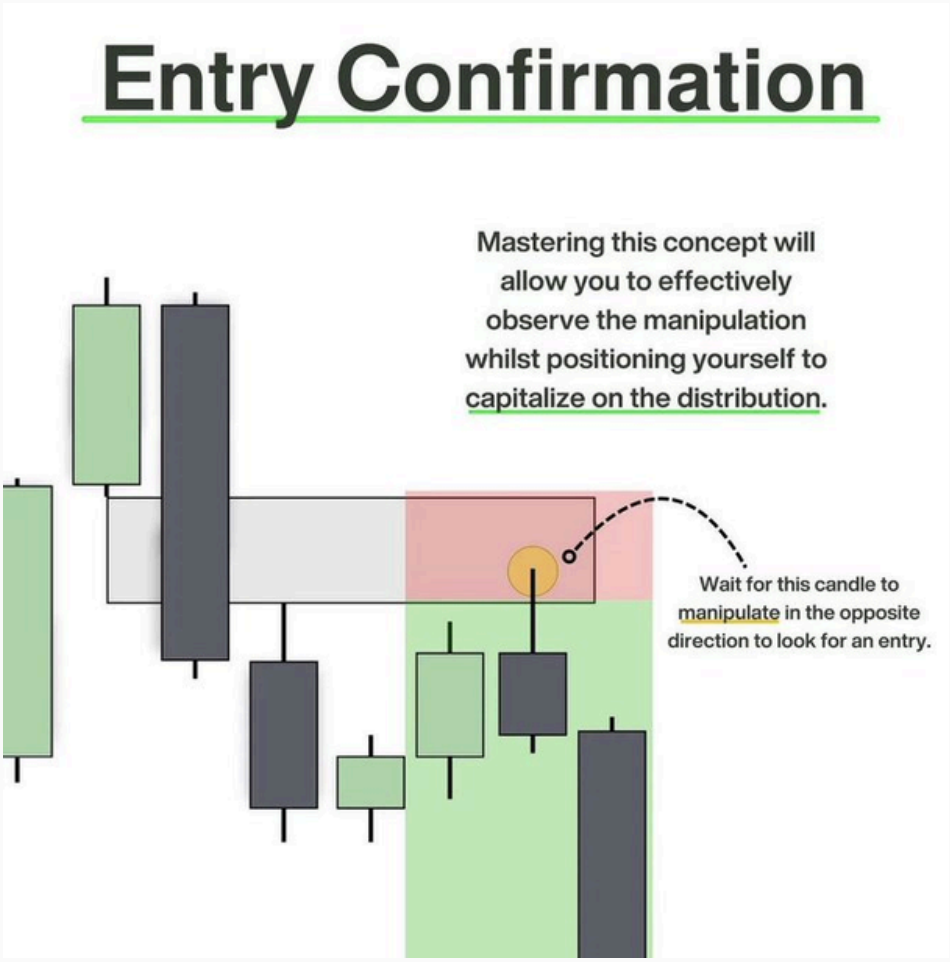

Even a single large buy or sell order can cause a significant move, leading to increased volatility and unpredictable price behavior.

IV. ENTRY CONFIRMATION

Before entering a trade, it's important to look for strong confirmation signals. Here are some of the most effective ones:

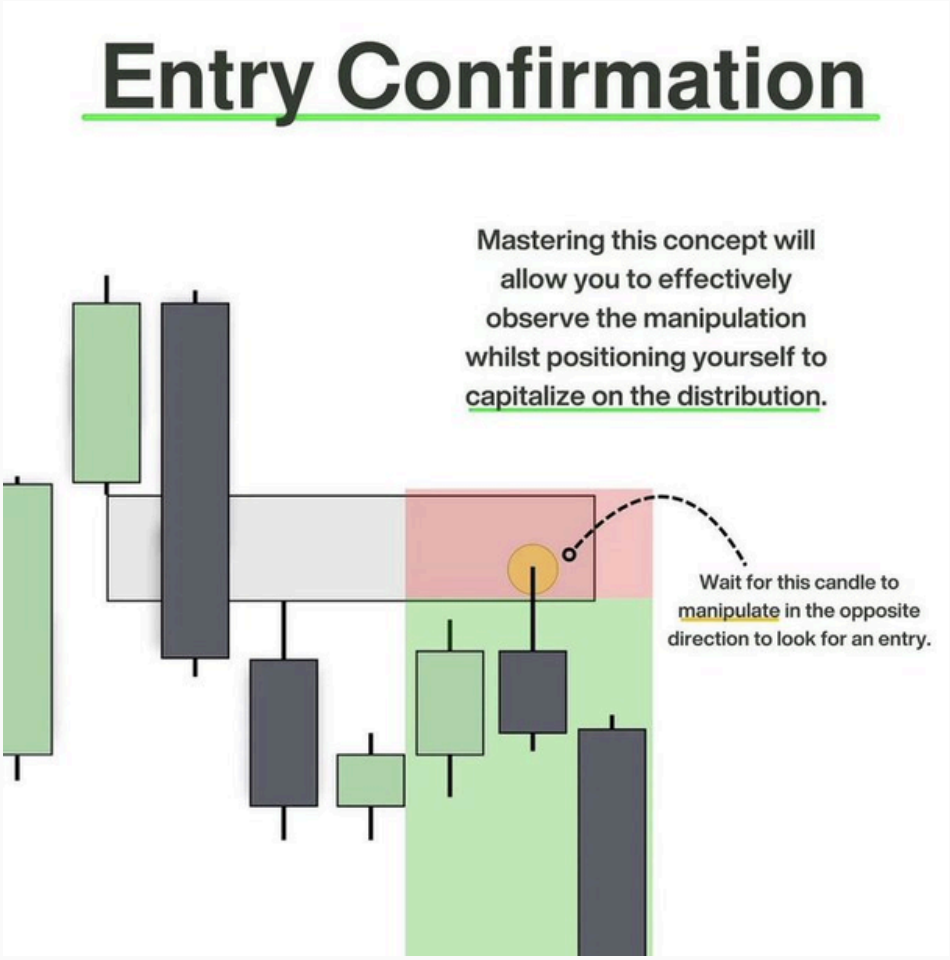

1. **Technical Indicators** – Tools like MACD, RSI, and Stochastic help identify momentum, overbought or oversold conditions, and potential trend shifts
2. **Support and Resistance** – Confirm entries near well-established levels where price has reacted in the past
3. **Trend Confirmation** – Ensure your entry aligns with the overall trend direction for higher probability setups
4. **Candlestick Patterns** – Look for patterns like engulfing candles, hammers, or dojis at key zones
5. **Fundamental and Volume Analysis** – Use news, market sentiment, and volume spikes to strengthen technical setups and spot real buying or selling pressure

ENTRY CONFIRMATION

Before entering a trade, it's important to look for strong confirmation signals. Here are some of the most effective ones:

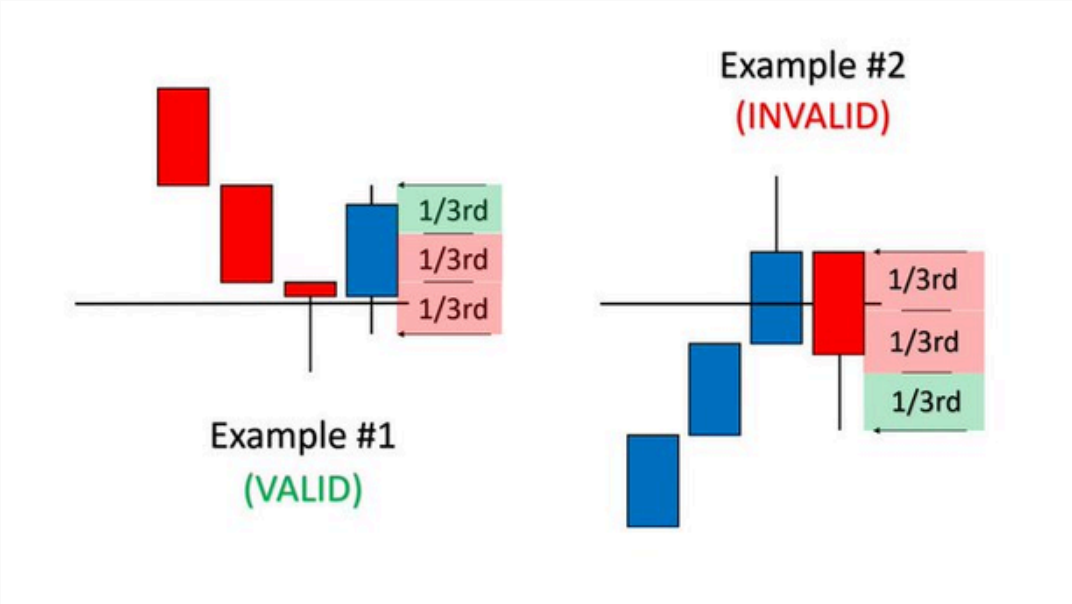

1. **Technical Indicators** – Tools like MACD, RSI, and Stochastic help identify momentum, overbought or oversold conditions, and potential trend shifts
2. **Support and Resistance** – Confirm entries near well-established levels where price has reacted in the past
3. **Trend Confirmation** – Ensure your entry aligns with the overall trend direction for higher probability setups
4. **Candlestick Patterns** – Look for patterns like engulfing candles, hammers, or dojis at key zones
5. **Fundamental and Volume Analysis** – Use news, market sentiment, and volume spikes to strengthen technical setups and spot real buying or selling pressure

ENTRY CONFIRMATION: LONG SETUP

In a long setup, a valid confirmation candle should meet two key conditions:

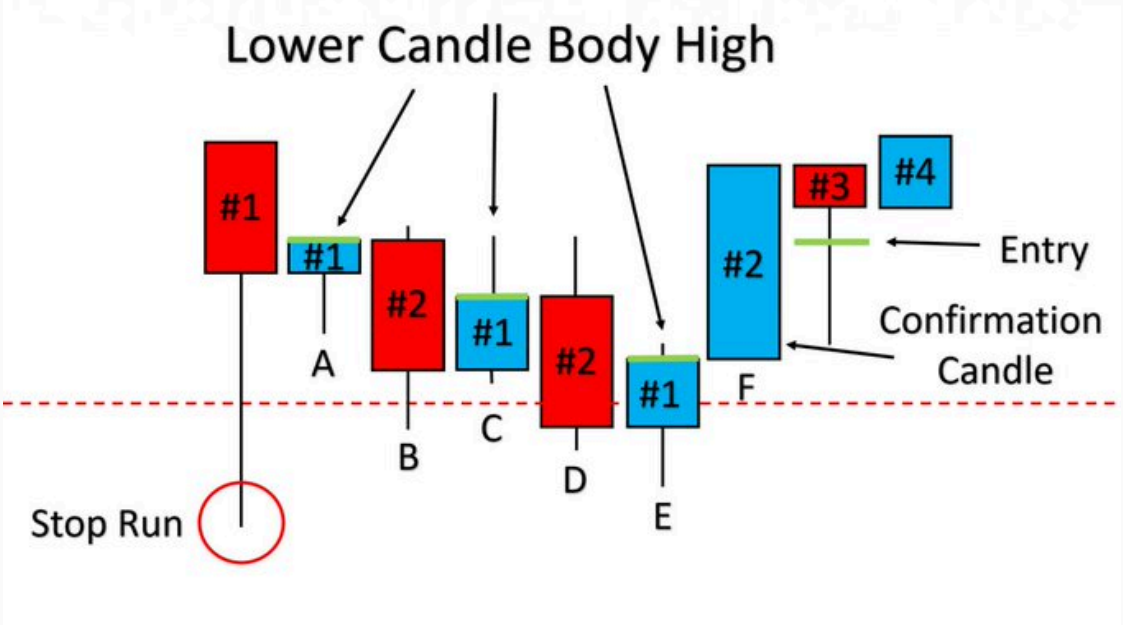

1. It must close above the body of the previous candle, showing clear bullish intent.
2. Ideally, it should also close in the upper one-third of its own range, indicating strong upward momentum and buyer control.

ENTRY CONFIRMATION: LONG SETUP

In this example, the entry setup follows these steps:

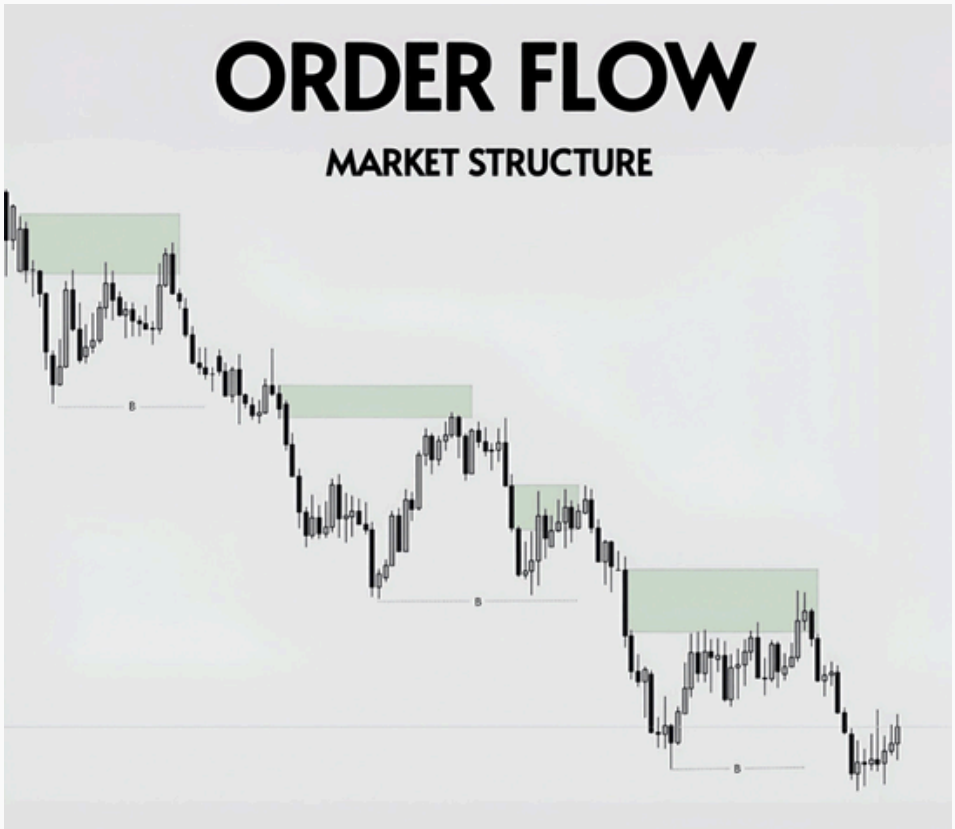

1. Wait for a stop run where price dips below support, sweeping sell-side liquidity.
2. Look for a bullish engulfing candle that closes with a full body covering the previous candle(s), signaling a strong reversal.
3. Watch for a bearish wick retest near the open of the bullish candle, confirming that buyers are defending the level.
4. Enter the trade after this retest, with a tighter stop and a clearer structure for the move.

V. MARKET STRUCTURE

Understanding market structure is key to recognizing the flow of price and spotting high-probability trade setups. Here's how to identify it:

1. **Mark FVGs on Higher Timeframes** – These gaps often act as strong resistance or support zones.
2. **Identify the Lower Low (LL) of the structure** – This helps define the current bearish trend or a break in structure.
3. **Use FVGs as Resistance** – When price revisits these areas, expect potential rejection.
4. **Treat the Lower Low as Support** – After the break and shift in structure, previous lows may hold as new support.
5. **Always identify market structure on Higher Timeframes (HTF)** – It gives a clearer picture of the trend and helps you avoid false signals from lower timeframes.

MARKET STRUCTURE: HOW TO TRADE IT

Before taking any trade, always check the market structure, preferably on the 4H or 1D timeframe. This helps you understand the broader context and avoid trading against the trend.

By identifying whether the market is in an uptrend or downtrend, you can align your entries with the dominant direction. In an uptrend, look for higher highs and higher lows. In a downtrend, look for lower highs and lower lows.

The key is to follow the trend until clear signs of a reversal appear. Trading with the structure increases your probability of success and reduces unnecessary losses.

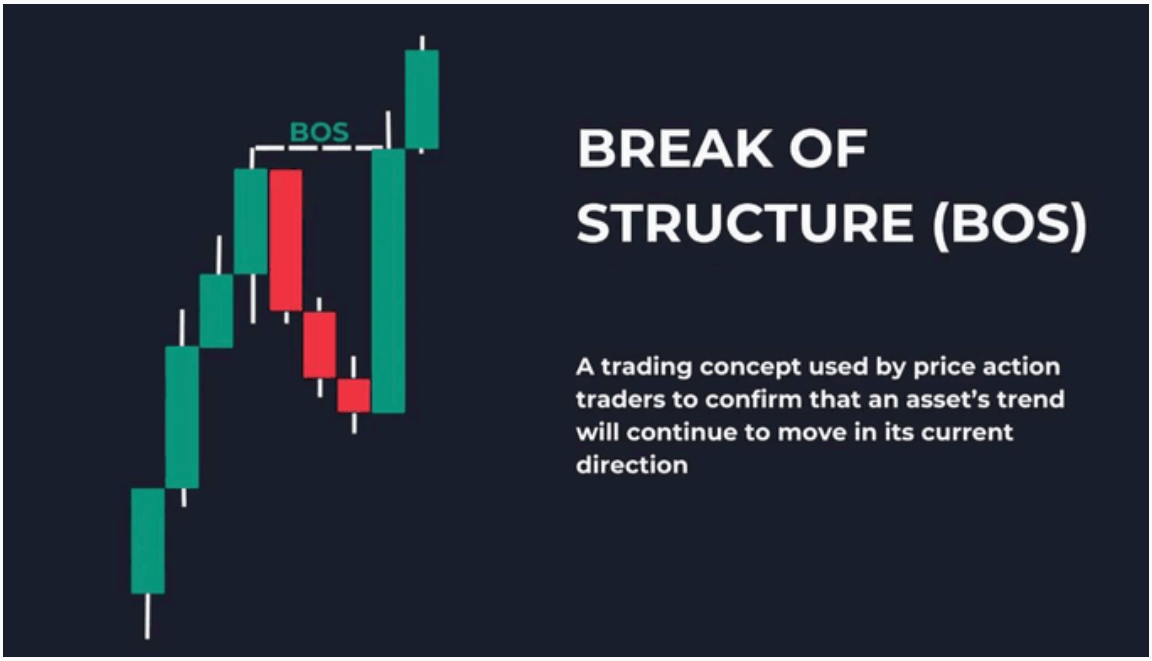

VI. BREAK OF STRUCTURE (BOS)

A Break of Structure (BOS) is a key signal used to confirm that the current market trend is likely to continue in the same direction. It marks a shift in price action and validates trend strength.

A **Bullish** BOS occurs when price breaks above a previous high, showing that buyers are in control and that higher highs are forming. This often confirms continuation in an uptrend.

A **Bearish** BOS happens when price breaks below a previous low, indicating that sellers have taken over and that lower lows are forming. This suggests the downtrend is intact.

BREAK OF STRUCTURE (BOS)

Bullish and Bearish BOS are not direct entry or exit signals. Instead, they serve as confirmation that the current market structure is likely to continue.

A Bullish BOS confirms that the uptrend remains intact, while a Bearish BOS signals the continuation of a downtrend.

BREAK OF STRUCTURE (BOS)

A Bullish BOS is identified by first spotting a higher low (HL) compared to the previous low.

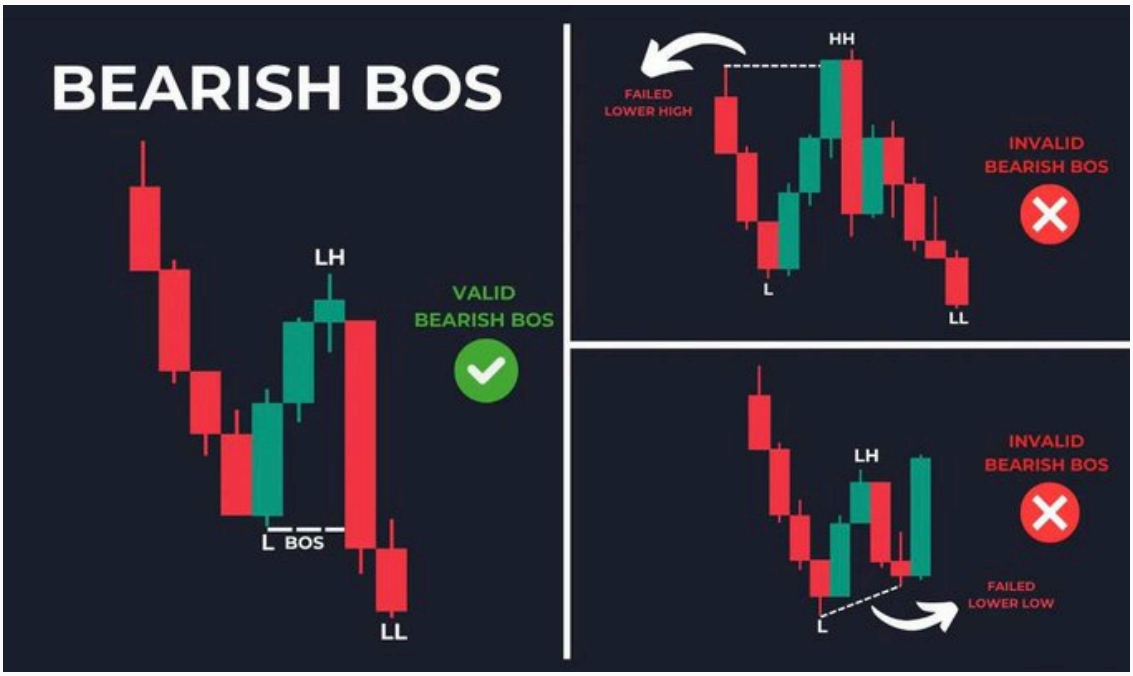

Then, wait for price to break above the previous high, forming a higher high (HH) — this confirms the bullish market structure.

BREAK OF STRUCTURE (BOS)

A Bearish Break of Structure is identified by first spotting a lower high (LH) compared to the previous high.

Then, price must break below the previous low, forming a lower low (LL) — this confirms a bearish market structure.

VII. HOW TO IDENTIFY A TREND

Understanding market structure (MS) is essential for spotting whether the market is in a bullish or bearish trend.

A bullish market structure is identified by a continuous series of higher highs (HH) and higher lows (HL). This shows strong upward momentum and buyer control.

A bearish market structure is marked by a sequence of lower highs (LH) and lower lows (LL), signaling selling pressure and downward momentum.
Recognizing these patterns allows traders to align with the trend and make more informed entry and exit decisions.

HOW TO IDENTIFY A TREND

Bullish Market Structure is defined by a sequence of higher highs (HH) and higher lows (HL). A bullish trend is confirmed when you spot two or more HHs and at least one HL on the chart, showing that buyers are in control.

Bearish Market Structure is made up of lower highs (LH) and lower lows (LL). When you see two or more LHs and LLs, it usually means the market is in a downtrend and sellers are dominating.

HOW TO IDENTIFY A TREND

A sideways trend happens when price moves horizontally, showing no clear upward or downward direction. This occurs when the forces of supply and demand are nearly balanced, leading to a range-bound market.

Sideways trends often appear during consolidation periods, where the market pauses before either continuing the previous trend or reversing into a new one. Traders typically wait for a breakout from the range to confirm the next move.

VIII. HOW TO CHART FROM START

Before placing any lines or levels, start by identifying the market structure (MS). Ask yourself: Is the market bullish or bearish? This will guide how you approach the chart.

Begin by drawing support levels first, starting from the bottom of the chart and working your way up. It's usually easier to identify a strong bottom than a top, especially in volatile markets.

Always remember, charts are read from left to right. Focus on how price has moved over time to understand current conditions and anticipate future moves. Let structure lead your analysis before adding tools or indicators.

HOW TO CHART FROM START

In this chart, we observe a bullish price action.
Start by drawing the range where price has been moving, marking the key support and resistance levels that contain the price.

Next, identify the point where the bullish trend begins and label it clearly. Look for a series of higher lows (HL) and higher highs (HH). These are the main signals that confirm a bullish market structure.

By simply tracking HL and HH, you can recognize that the market is trending upward, helping you align your analysis and trade direction.

HOW TO CHART FROM START

To build a chart from scratch, follow these key steps:

1.Identify the support level

- Find where price has bounced previously. This area acts as your base and helps define your invalidation point if price breaks below.

2. Mark the possible resistance

- Spot the level where price could face selling pressure and may retrace. This helps in planning your take-profit or exit zones.

3. Determine the current trend

- Look at the overall structure of the chart. Is price forming higher highs and higher lows (bullish), or lower highs and lower lows (bearish)? This gives you direction for your trading setup.

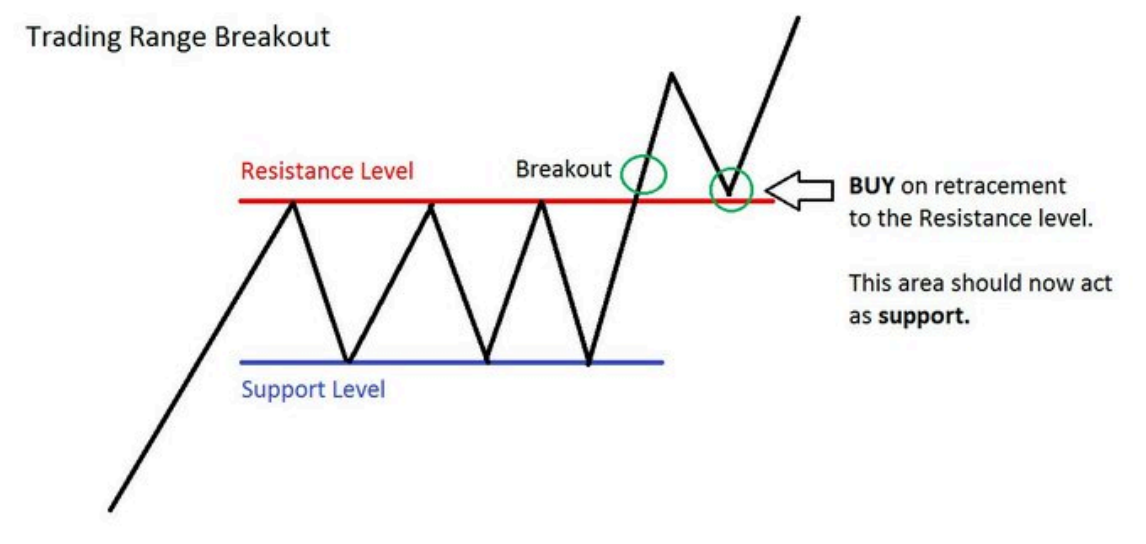

IX. HOW TO TRADE BETWEEN RANGES

A trading range is the area between the high and low prices of an asset over a specific period. It represents a phase of consolidation where price moves sideways, showing no strong trend direction.

Breakouts above the range or breakdowns below become more reliable when confirmed by high trading volume, signaling strong interest from buyers or sellers.

Trading ranges also help assess relative risk. Tighter ranges suggest low volatility and less risk, while wider ranges indicate higher volatility and increased uncertainty.

HOW TO TRADE BETWEEN RANGES

In This Example

- Support ($52): Consider entering long positions near this level. Place your stop loss slightly below to manage risk in case support fails.

- Resistance ($154): This is where you can exit long positions or consider entering short positions. Place your stop loss above resistance to protect against false breakouts.

- Breakout Confirmation: If price breaks above resistance or below support, wait for volume confirmation before entering a trade. This helps filter out fake breakouts and improves trade reliability.

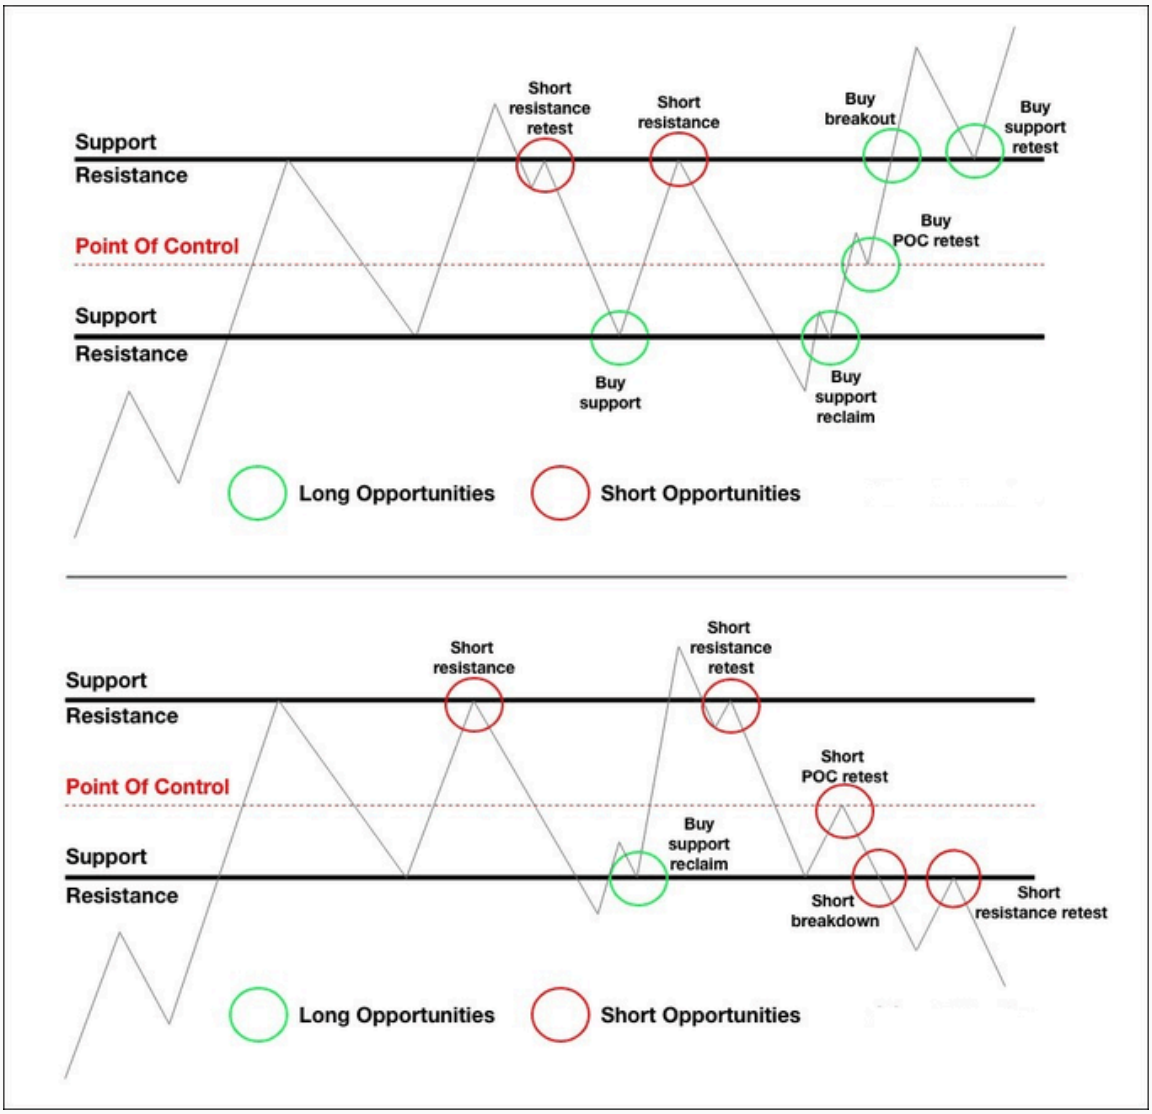

HOW TO TRADE BETWEEN RANGES

Traders can look for opportunities to enter in the direction of a breakout or breakdown from a trading range. These moves can signal the start of a new trend if supported by strong market behavior.

To confirm whether the breakout is valid, it's important to use additional indicators such as volume, RSI, or moving averages. These tools can help filter out false signals.

However, the most reliable confirmation remains price action (PA). Observing how price behaves around the edges of the range gives the clearest signal of market intent.

X. HOW TO OPEN A SHORT POSITION

1. Find a key level where price has previously reacted or reversed.
2. Draw your Fibonacci levels from the swing high to the swing low.
3. Wait for a short opportunity as price retests a major Fibonacci level.
4. Take the short with a stop loss placed above the key level.

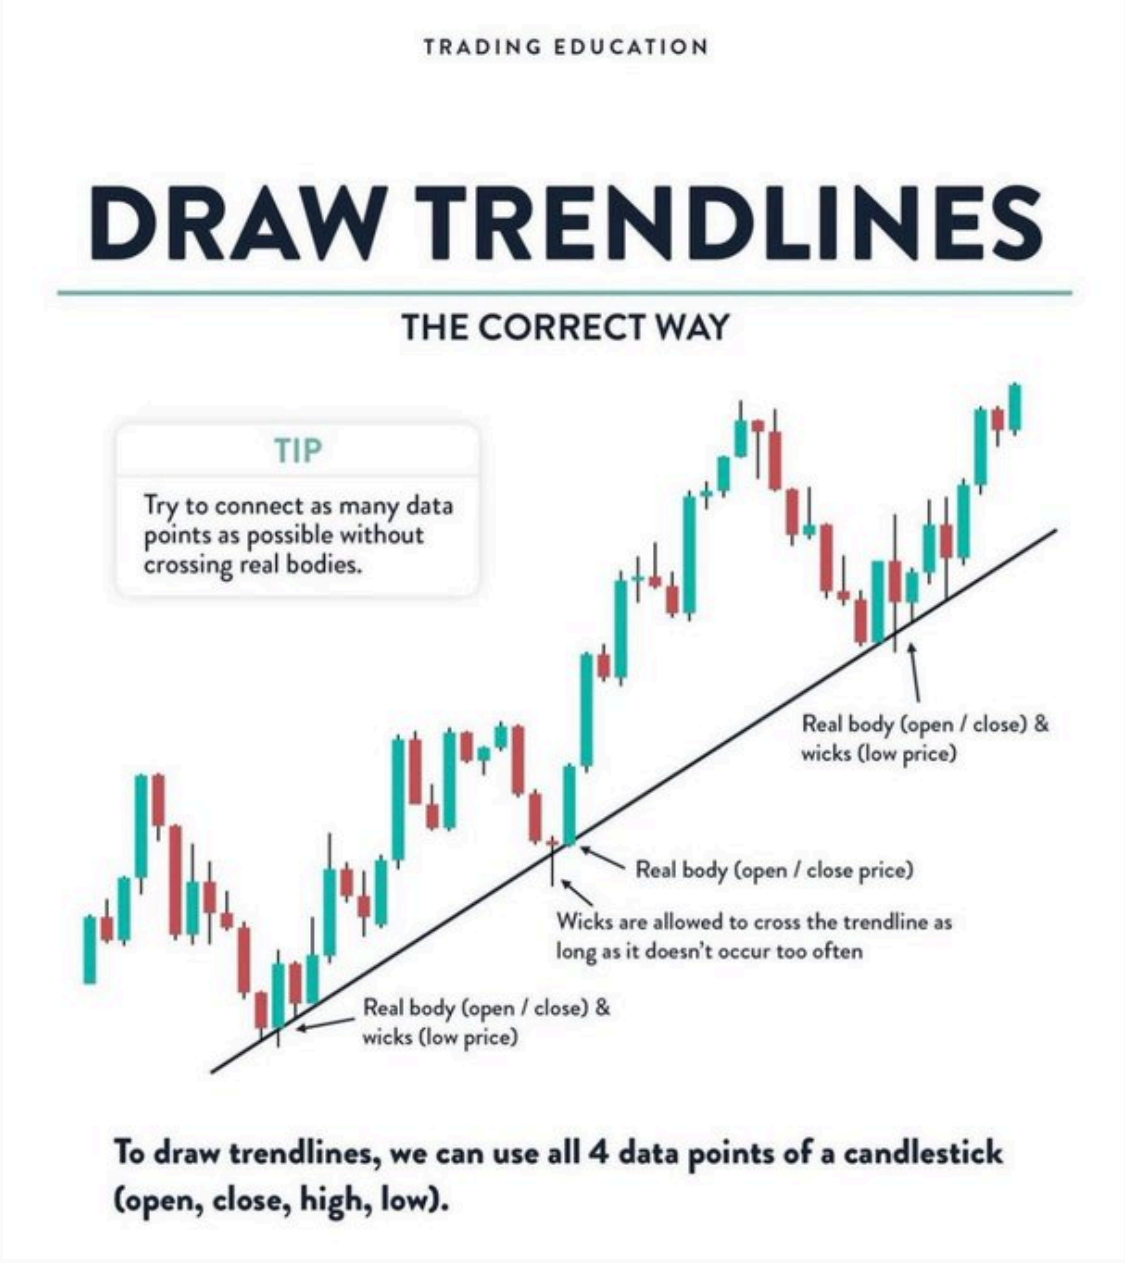

XI. TRENDLINES

Trendlines are one of the most basic and widely used tools in technical analysis.

They connect a series of higher lows in an uptrend or lower highs in a downtrend, helping to visualize the overall direction of price.

Trendlines also help traders spot potential entry and exit points, especially when price respects or breaks the line.

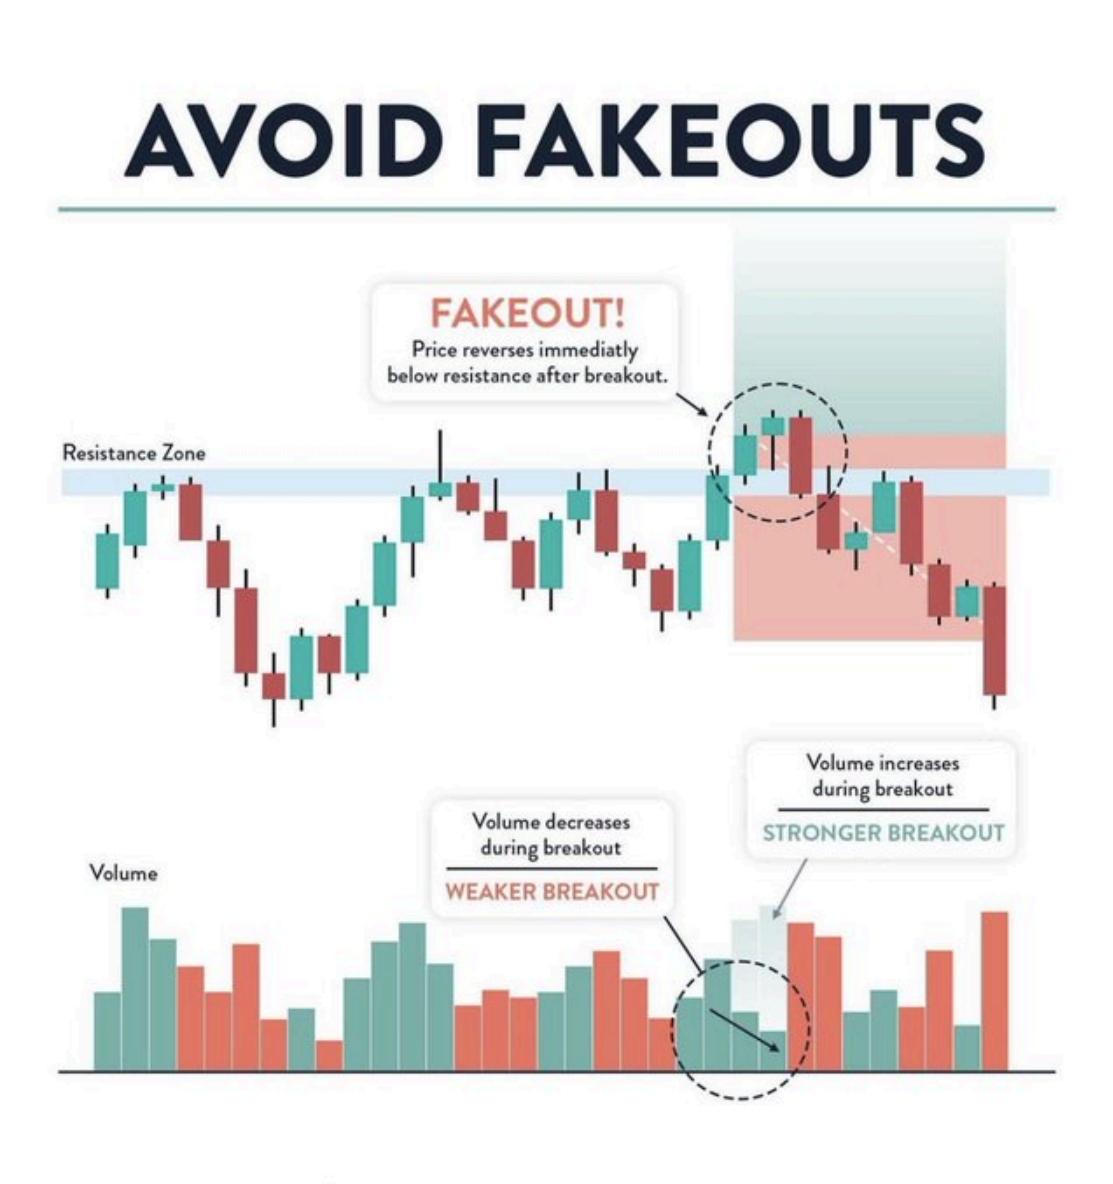

TRENDLINES: HOW TO TRADE THEM

1. Mark the swing points – Use lower highs (LH) for a bearish trendline and higher lows (HL) for a bullish trendline.
2. Draw the trendline – Connect the swing points with a straight line to define the trend.
3. Wait for a breakout and retest – Enter after price breaks and retests the trendline for confirmation.
4. Set your stop loss and take profit – Place SL beyond the retest and TP at the next key level.

XII. HOW TO AVOID FAKEOUTS

1. **Watch the volume during breakouts** – A strong breakout should be backed by increasing volume.
2. **Be cautious of low-volume breakouts** – If volume is decreasing while price breaks out, it's likely a weak move and may lead to a fakeout.
3. **Always monitor volume** – Volume is one of the most reliable confirmations for the strength and validity of a breakout.

UNDERSTANDING MARKET LIQUIDITY

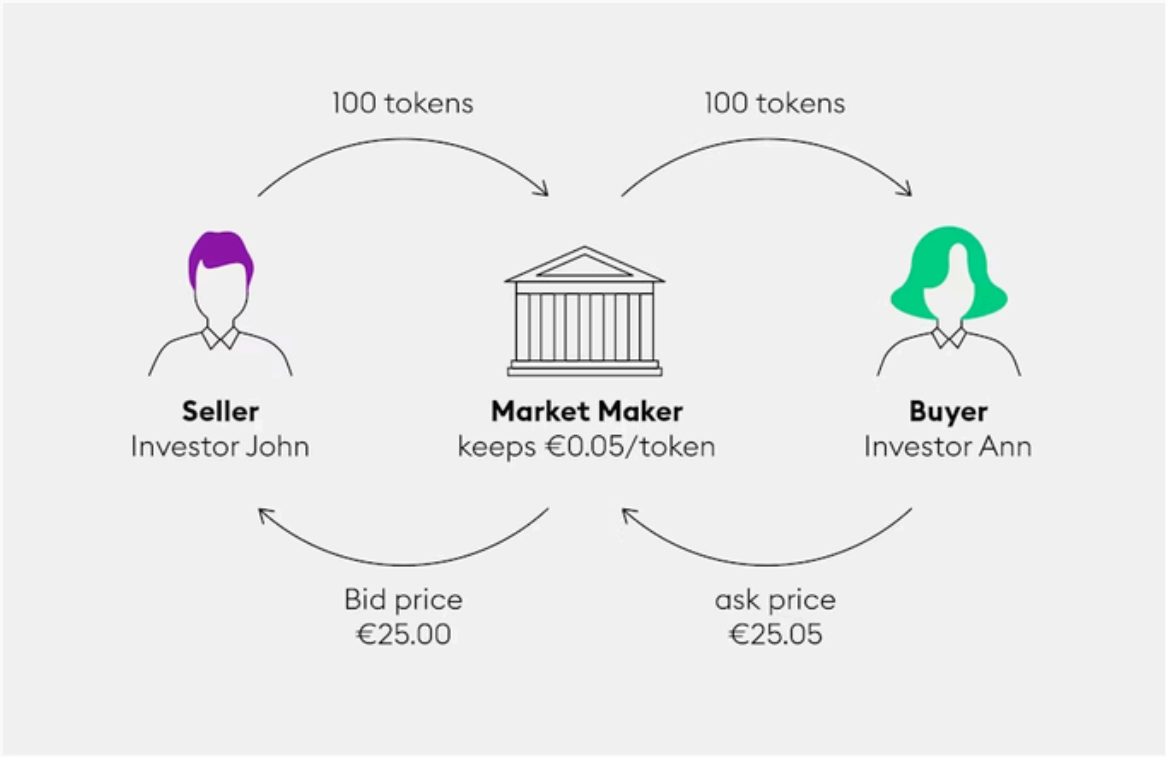

I. WHAT IS LIQUIDITY?

Liquidity is the sum of all buy and sell orders sitting at specific price levels in the market. These orders form liquidity zones that make it easier or harder for trades to be filled. The more orders stacked around a price, the more liquid that level becomes.

Liquidity is found at almost every high and low on a price chart. This is because traders tend to place buy and sell orders, as well as stop losses, near these areas. For example, after a strong price move upward, many traders will set sell orders at the previous high while others place stop losses just above it. This creates a concentration of orders, or liquidity, at that point.

Smart money, such as institutional traders or experienced market participants, often target these liquidity zones. They may push the price into these areas to trigger stop losses or collect large amounts of orders to fill their positions. If there are a lot of stop losses below a support level, smart money might drive the price down just enough to activate them, take the liquidity, and then reverse the trend upward.

II. WHAT ARE MARKET-MAKERS?

Market Makers are large participants in the financial markets, often referred to as whales due to the size of their capital. These entities can include banks, hedge funds, and specialized trading firms that provide constant buy and sell offers across various assets.

Their main role is to ensure that liquidity is available at all price levels. This means they are willing to buy when others are selling and sell when others are buying, helping to keep the market functioning smoothly.

Market Makers have enough capital to guarantee the exchange that there will always be supply and demand in the order book, even in volatile conditions. This is essential for reducing the spread between the bid and ask prices, which benefits all market participants by creating more efficient trading conditions.

Without market makers, it would be harder to enter and exit positions quickly, especially for large volumes, and the market would experience greater price slippage and instability.

III. WHERE IS LIQUIDITY?

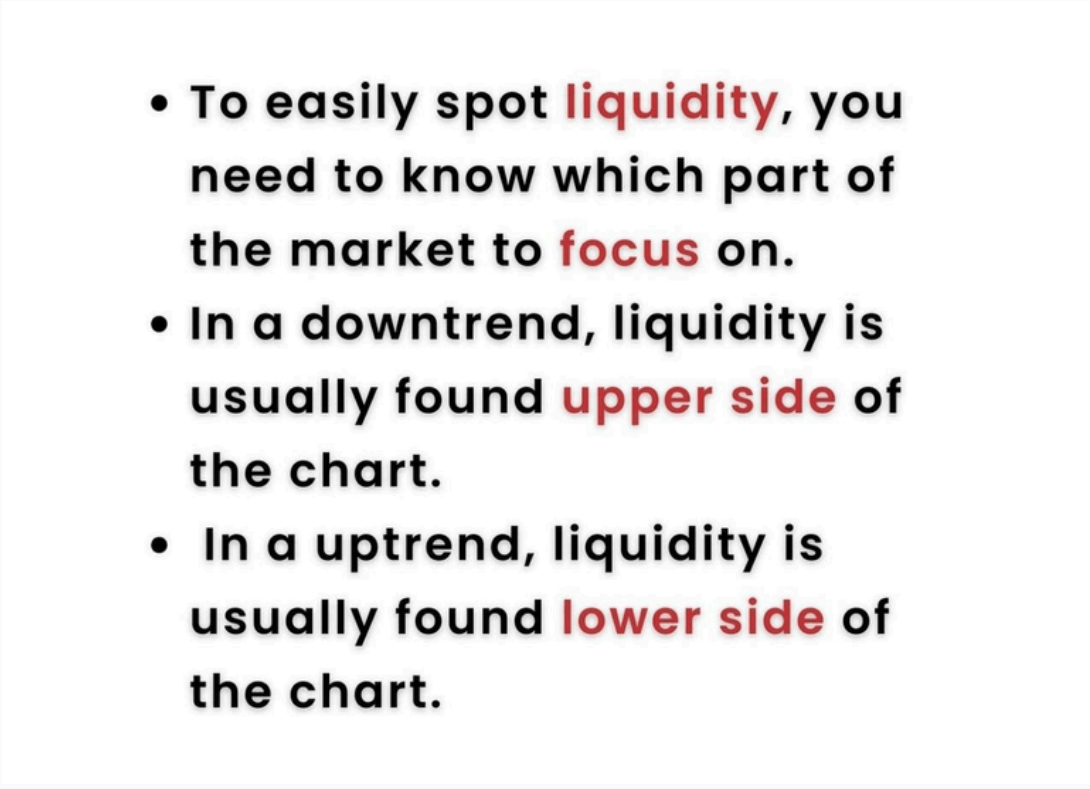

To find liquidity, start by identifying the market trend. The trend tells you where traders are placing most of their stop losses and pending orders.

In a **downtrend**, liquidity is usually on the upper side of the chart. Traders who are shorting place their stop losses above recent highs, creating clusters of buy orders. Smart money often drives price upward to hit these stops, collect liquidity, then continue the downward move.

In an **uptrend**, liquidity builds on the lower side of the chart. Stop losses from long positions stack below higher lows. Price may dip into these areas to grab liquidity before pushing higher again.

By following the trend and watching where highs and lows form, you can spot likely liquidity zones and avoid getting caught in fake breakouts or stop hunts.

Save this picture below as your guide:

WHERE IS LIQUIDITY?

Liquidity draws price in, especially around imbalances, which are areas where buying and selling were uneven. These usually show up as strong, one-directional candles. The market often returns to these zones to fill leftover orders and rebalance.

Price gravitates toward imbalances

- These zones act like magnets. Price tends to revisit them before continuing its move, making them key areas to watch.

Use imbalances as support and resistance for scalping

- On lower timeframes, imbalances can cause sharp reactions. They serve as great spots for quick entries and exits.

Identify imbalances on higher timeframes, refine on lower ones

- Start with the 4H or daily chart to mark major imbalances. Then drop to the 1H or 15M to fine-tune your entries.

Example: If you spot an imbalance on the 4H chart, wait for price to revisit that zone. Use the 1H chart to look for reaction and confirmation before entering a trade.

IV. TYPES OF LIQUIDITY: BSL & SSL

There are two main types of liquidity to watch for in the market: Buy-side Liquidity (BSL) and Sell-side Liquidity (SSL). These represent areas where traders' stop losses are clustered.

BSL refers to levels where short sellers have placed their stop losses, usually above recent highs or resistance. When price moves up and hits these stops, it triggers buy orders that create liquidity for smart money to sell into. These levels often get targeted during liquidity grabs in a downtrend.

SSL refers to levels where long traders have set their stop losses, often below recent lows or support. When price dips into these zones, it triggers sell orders, allowing large players to buy at better prices before pushing price back up.

TYPES OF LIQUIDITY: BSL & SSL

There are two main types of liquidity to watch for in the market: Buy-side Liquidity (BSL) and Sell-side Liquidity (SSL). These represent areas where traders' stop losses are clustered.

BSL refers to levels where short sellers have placed their stop losses, usually above recent highs or resistance. When price moves up and hits these stops, it triggers buy orders that create liquidity for smart money to sell into. These levels often get targeted during liquidity grabs in a downtrend.

SSL refers to levels where long traders have set their stop losses, often below recent lows or support. When price dips into these zones, it triggers sell orders, allowing large players to buy at better prices before pushing price back up.

TYPES OF LIQUIDITY: BSL & SSL Examples

In this example, I will illustrate how price can sweep both sides of liquidity in a single move.

First, price dips below a recent low, sweeping sell-side liquidity (SSL) by triggering the stop losses of long traders. This move shakes out weak hands and allows smart money to accumulate long positions at a discount.

After sweeping the lows, price leaves behind a large pool of buy-side liquidity (BSL) sitting above recent highs. These are stop losses placed by short sellers expecting the downtrend to continue.

Next, price makes a sharp move upward, triggering those short-side stops. This stop-hunt clears out the remaining liquidity, and we then see a reversal as price gravitates toward structural liquidity, such as a major supply or resistance zone.

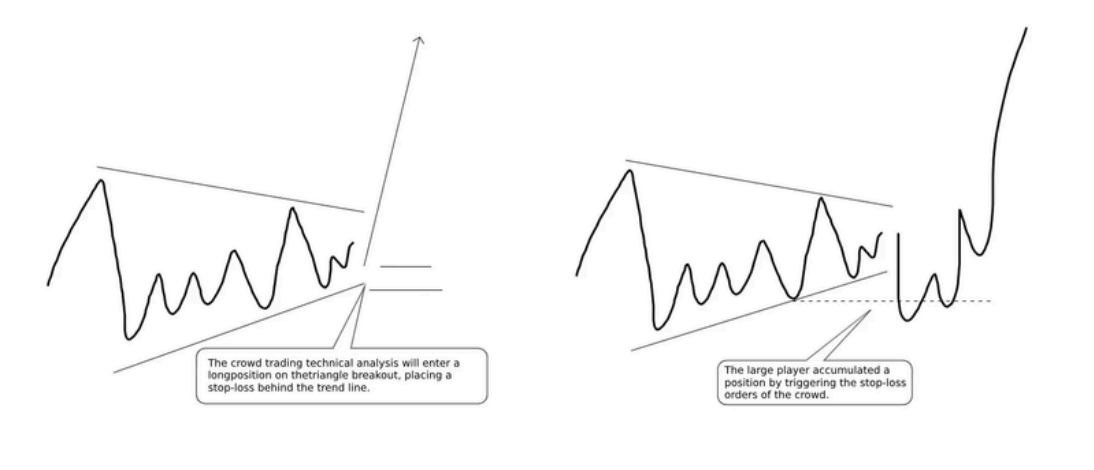

V. TYPES OF LIQUIDITY: OTHER TOOLS

There are dozens of tools that large players use to manipulate price action and trap retail traders. Common patterns like trendlines, bull flags, bear flags, wedges, and triangles are often used not just for technical analysis, but as psychological traps. Many traders enter or exit based on these patterns, creating predictable zones for stop losses and pending orders.

Liquidity tends to build up both above and below equal highs and lows, since these areas attract breakout traders and stop orders. But liquidity also exists within the range—in the form of internal highs and lows, fair value gaps, and unfilled orders.

If there is liquidity, the market is drawn to it like a magnet. Price will often make a move to grab that liquidity before continuing in its intended direction. This is why understanding where liquidity lies is more important than relying solely on patterns or indicators.

VI. TYPES OF LIQUIDITY: PDH & PDL

PDH (Previous Day High)

PDH refers to the highest price reached during the previous trading day. It is often used as a key resistance level. Many traders place sell orders, breakout entries, or stop losses around this area. Because of this, PDH becomes a common target for liquidity grabs before the market decides on its next move.

PDL (Previous Day Low)

PDL is the lowest price recorded during the previous trading day. It is usually seen as a support level and often attracts buy orders or stop losses from traders holding long positions. Just like PDH, the PDL can act as a magnet for price, especially when smart money seeks to tap into sell-side liquidity before reversing the trend.

Both PDH and PDL are important because they represent zones where many traders make decisions, making them high-probability areas for manipulation or continuation.

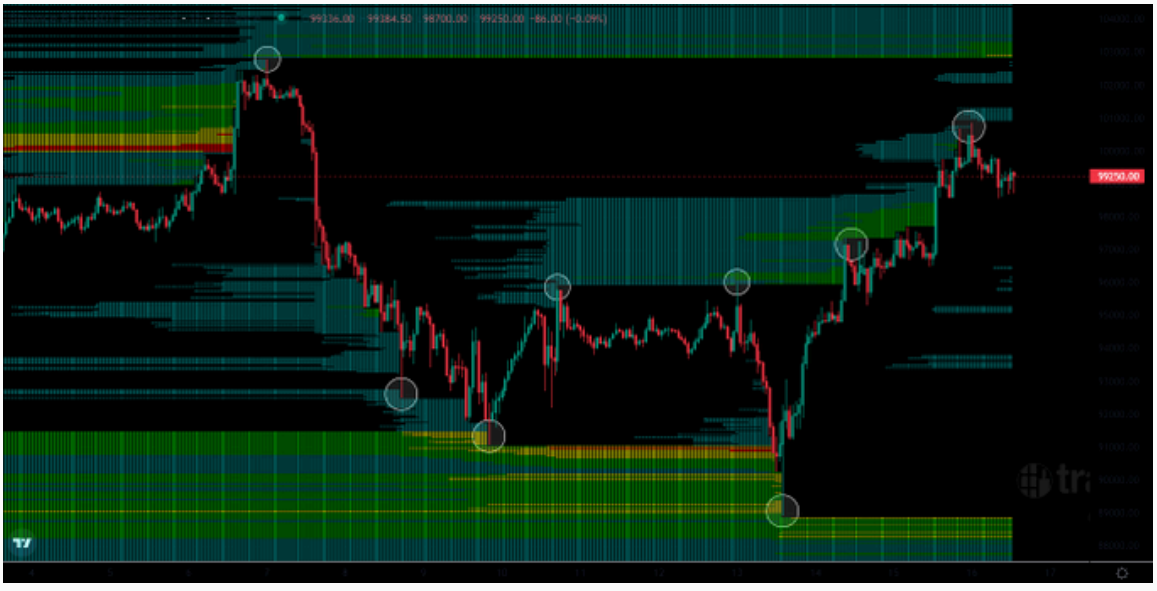

VII. LIQUIDATION HEATMAP

A Liquidation Heatmap is a visual tool that shows where liquidity is concentrated in the market. It highlights zones where large clusters of stop losses or liquidation levels are located, helping traders predict where price might be drawn.
These maps are based on data from leveraged positions and are interpreted through color, brightness, and size.

- Brighter areas indicate higher concentrations of liquidity.
- Darker zones show less activity.
- The size of a zone reflects how many positions are stacked there.

Heatmaps represent the distribution of liquidity and order flow, revealing where smart money might aim to trigger liquidations. For example, if there's a bright cluster just above a resistance level, price may spike up to that area before reversing.

Traders use heatmaps to anticipate stop hunts, fakeouts, and high-probability reversal zones by reading how other participants are positioned in the market.

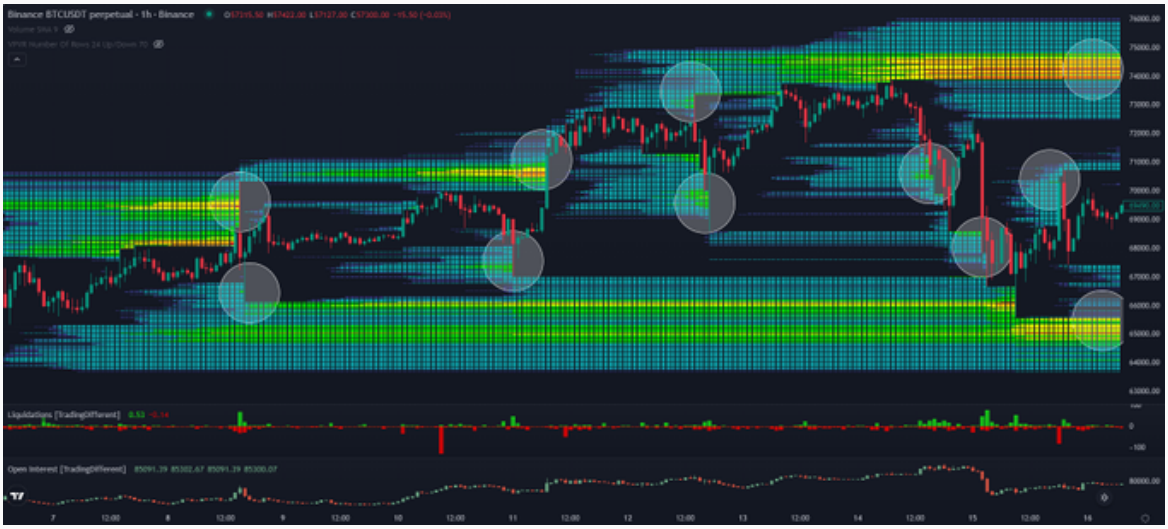

LIQUIDATION HEATMAP

This price action is a clear visual representation of how price sweeps both sides of a range, targeting liquidity above the highs and below the lows. These movements are not random. They are designed to trigger stop losses and collect orders before choosing a direction.

Heatmaps are useful tools for identifying support, resistance, and potential trend changes. By showing where traders are positioned, heatmaps reveal high-risk areas where liquidity is concentrated.

Price will always be attracted to zones with unswept liquidity. If stop losses or open interest are stacked in a specific area, the market will likely move there to collect that liquidity before continuing or reversing.

VIII. HOW TO TRADE USING HEATMAPS

1.Identify liquidity pools within market structure

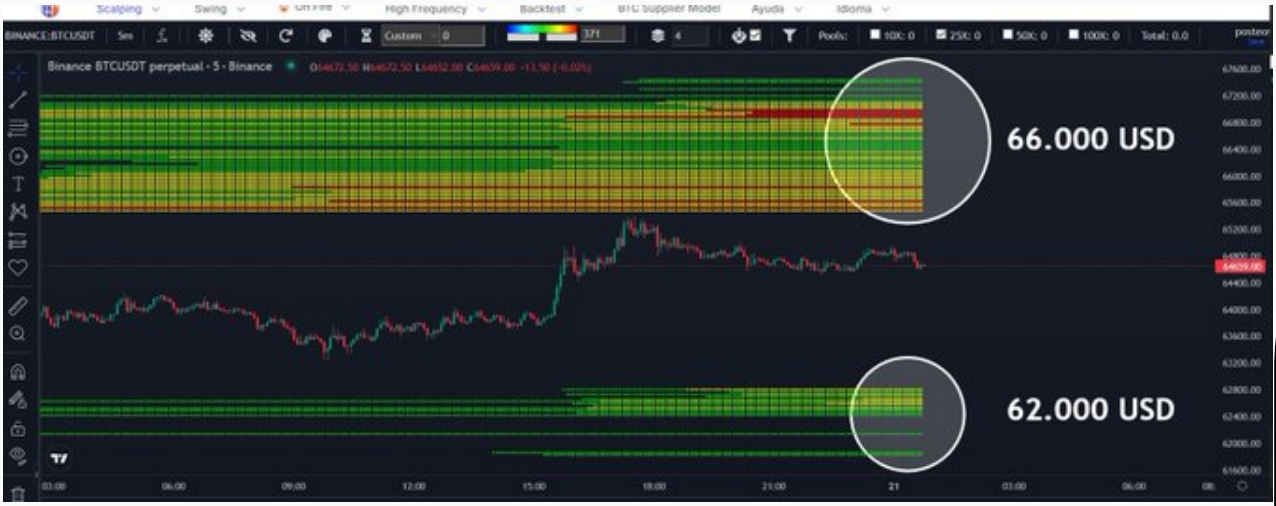

- Look for areas on the heatmap where large bubbles or bright zones appear. These represent clusters of orders where liquidity is building, usually around key highs, lows, or consolidation zones.

2. Execute trades when price enters those liquidity zones

- Wait for price to approach or tap into these highlighted areas. These zones often trigger strong reactions, giving opportunities for entries based on reversals or continuations.

3. Use these levels for stop loss or invalidation

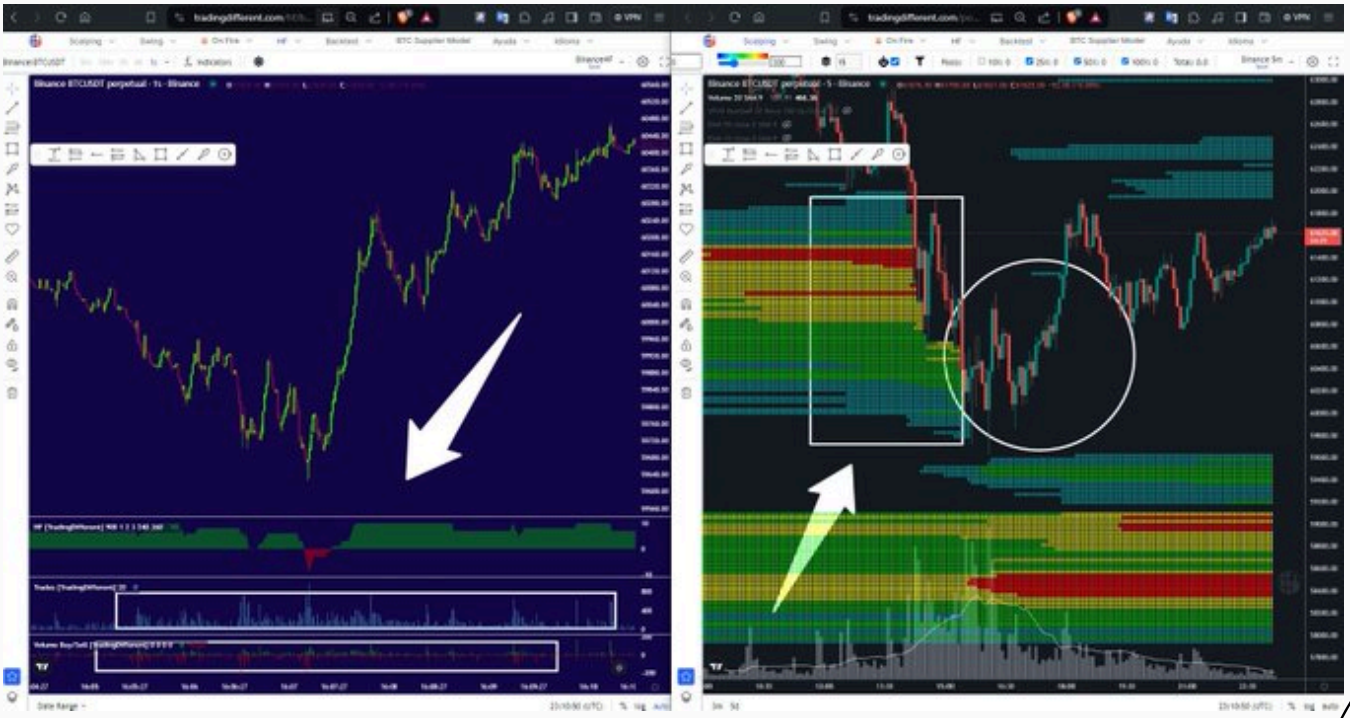

- Set your stop loss just beyond the liquidity zone. If price moves through it without reaction, the setup may be invalid, and exiting the trade helps control risk.

HOW TO TRADE USING HEATMAPS

After Bitcoin sweeps the liquidity of overleveraged traders (such as 25x, 50x, and 100x positions), it often bounces at the edge of the liquidity pool. This bounce signals that the market has absorbed those positions and may be ready to reverse or continue in a new direction.

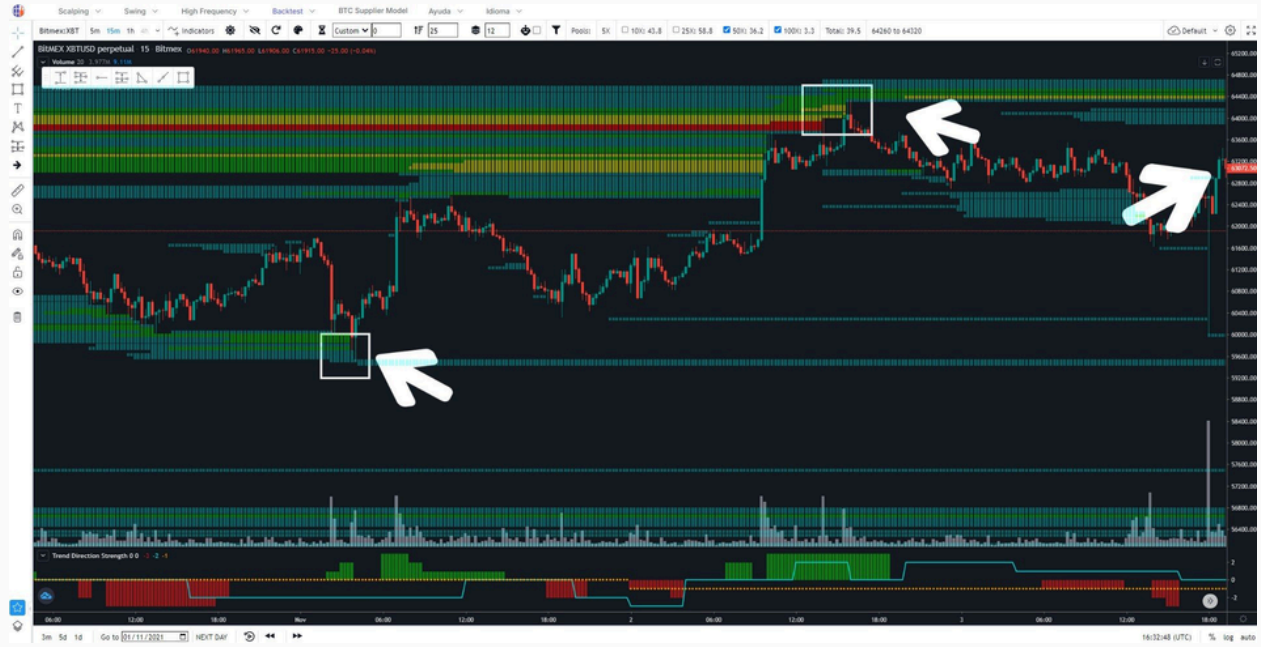

These moves are frequently followed by aggressive high-frequency (HF) buying activity, which adds momentum and confirms the shift.

HOW TO TRADE USING HEATMAPS

- Take LONG positions in the first liquidity box
  - Price takes out sell-side liquidity and shows signs of buying pressure. This suggests smart money may be entering. Look for confirmation before entering a long.

- Take SHORT positions in the second liquidity box
  - Price takes out buy-side liquidity by sweeping recent highs. Once the prior high before the higher high is lost, it signals weakness. This is a good spot to consider entering a short.

HOW TO TRADE USING HEATMAPS

Using a High Frequency (HF) tool, you can observe rapid market activity that reveals clear intention.

In this case, there is visible buy-side pressure pushing Bitcoin toward the upper liquidity zone, as shown by the indicator. With thousands of trades being executed per second, the probability of sweeping most or all of the liquidity pool increases.

This kind of activity signals strong momentum. Traders can use it to anticipate where price is headed next and prepare for entries near the edge of the liquidity zone.

HEATMAPS: POOLS OF LIQUIDITY

This price movement on Bitcoin happened last year.

Price dumped from $63,000 without retesting the upper liquidity pool, which led to the liquidation of many long positions. Bitcoin continued to fall until it reached a zone with significant short-side liquidity.

After liquidating the shorts, $BTC bounced. On the 4H chart, it tapped into both the upper and lower liquidity pools. Price skipped the upper pool at first, then swept the lower one before reversing.

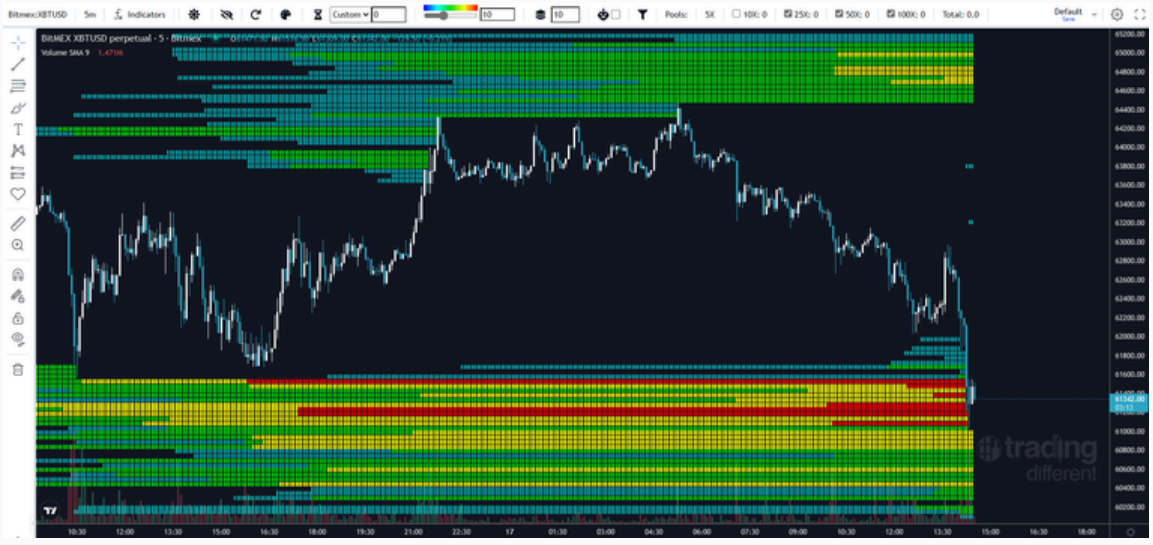

HEATMAPS: POOLS OF LIQUIDITY

Price fails to sweep the upper liquidity. After a rapid pullback, the movement that follows becomes staggered and weak.

Eventually, price reaches and sweeps the pending liquidity in the lower pool. This clears out stop losses and triggers short-side liquidations.

Sometimes, price does not need to retest the upper liquidity before reversing and retracing. This is often due to a strong shift in order flow or sudden imbalance favoring the opposite direction.

IX. FIBONACCI LEVELS

Fibonacci retracement levels are specific prices shown as horizontal lines on a chart. These levels are used to identify potential areas where support or resistance might occur during a price move. They are based on the Fibonacci sequence and are widely used in technical analysis to forecast possible pullbacks or reversals.

There are two main types of Fibonacci tools:

- **Fibonacci Retracement** — Used to measure how far price may retrace after a strong move. Common levels include 38.2%, 50%, and 61.8%. These are often used to find entry points during corrections.

- **Fibonacci Expansion** — Also known as Fibonacci Extension, this tool projects future price targets beyond the current range. Traders use it to estimate how far a trend might extend after a breakout.

Both tools help traders plan entries, exits, and stop loss placements with better precision by aligning with potential reaction zones in the market.

FIBONACCI LEVELS

Before drawing Fibonacci levels, the first step is to identify the direction of the trend. The tool is only effective when used in the correct context.

In an **uptrend**, we are looking to measure a potential retracement or pullback, so we draw from the low to the high. This means selecting the swing low (the bottom of the move) and dragging the Fibonacci tool all the way to the swing high (the top of the move).

On your chart, this would look like attaching the Fibonacci tool to the bottom left and dragging it up toward the top right. This action plots retracement levels between the start and end of the move, helping you spot potential support zones where price might bounce before continuing higher.

FIBONACCI LEVELS

The **golden pocket** refers to the key Fibonacci retracement levels of **38.2 percent and 61.8 percent**. These levels are seen as strong areas of support and resistance and are widely respected by traders.

When price pulls back into this zone during a trend, it often reacts with either a bounce or a reversal. Many traders use this area to look for potential entry points, especially when it aligns with other confluences like trendlines or previous highs and lows.

The golden pocket helps identify key turning points in the market and is especially useful when planning trades based on pullbacks or corrections.

FIBONACCI LEVELS

Fibonacci levels become even more effective when combined with volume indicators, which help confirm the strength of support or resistance zones.

One of the best tools to pair with Fibonacci is the Fixed Range Volume Profile. This tool shows how much trading volume occurred at each price level within a selected range. By overlapping it with Fibonacci retracement zones, you can identify areas where both volume and Fibonacci align, increasing the chances of a strong market reaction.

This combination offers predictive insight into potential price movements, helping you spot key levels where buyers or sellers are likely to step in. It is especially useful for confirming entries, exits, and possible reversals.

X. LIQUIDITY SWEEP

A liquidity sweep happens when large institutions or market participants execute significant orders that intentionally move the price toward areas with high liquidity. These areas are usually filled with pending buy or sell orders, such as stop losses or limit orders. The goal of a liquidity sweep is to trigger those pending orders, collect the liquidity, and then reverse or continue the price move in the desired direction. It is a common strategy used by smart money to enter or exit positions efficiently.

There are two main types of liquidity involved in these sweeps:

- Buy-side Liquidity (BSL) is found above recent highs, where stop losses from short sellers are placed.
- Sell-side Liquidity (SSL) is found below recent lows, where long traders often set their stop losses.

Understanding these sweeps helps traders avoid getting trapped and align their entries with the behavior of smart money.

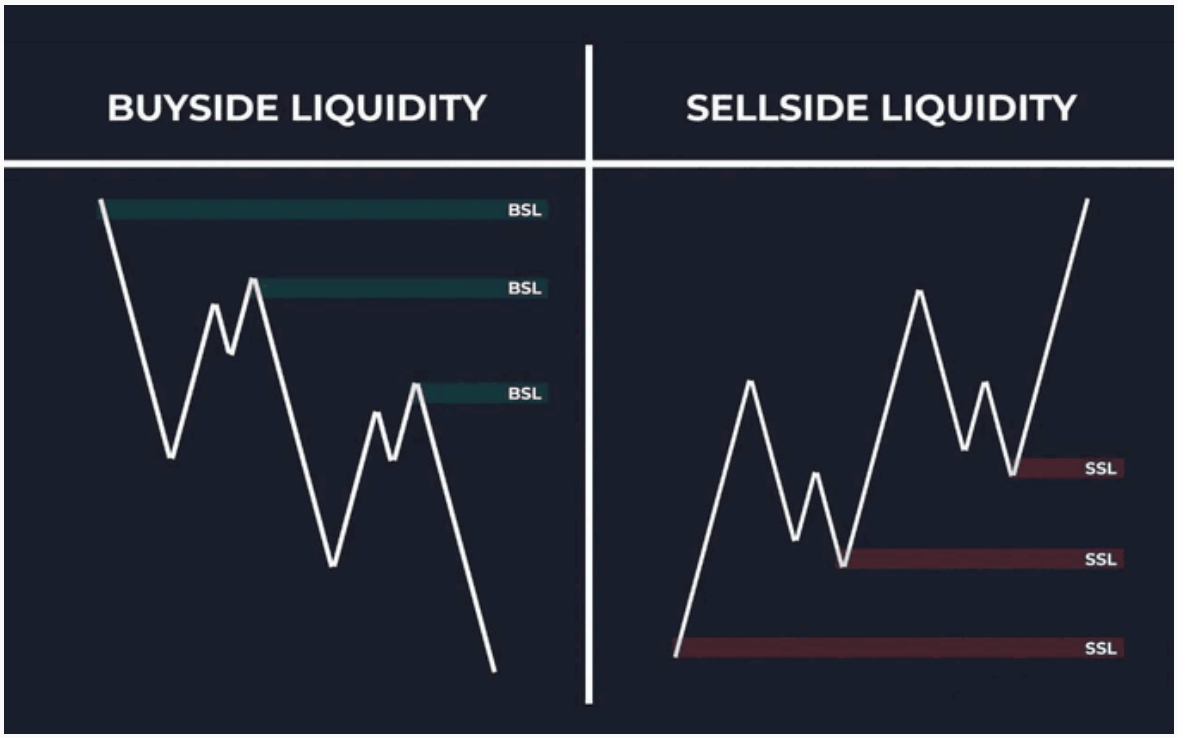

LIQUIDITY SWEEP

Buy-side Liquidity (BSL) refers to levels on the chart where short sellers have placed their stop losses. These are typically located above recent highs, as short positions get liquidated when price breaks above these points.

Sell-side Liquidity (SSL) refers to areas where long traders have set their stop losses, usually found below recent lows. When price dips into these zones, it triggers sell orders from long positions.

Both BSL and SSL are commonly found at the highs and lows of price ranges, making them frequent targets for liquidity sweeps. Identifying these zones can help traders anticipate potential stop hunts and position more effectively.

XI. LIQUIDITY GRAB

A **liquidity grab** is similar to a liquidity sweep but with a key difference. While a sweep is the act of moving price into liquidity zones to trigger orders, a liquidity grab specifically refers to the moment liquidity has already been taken. It marks the completion of that move, often followed by a reversal or significant reaction.

Liquidity grabs occur at key levels where buy-side or sell-side liquidity has just been swept. These levels usually hold many stop losses from traders who entered too early or too late. Once price taps into that liquidity and absorbs the orders, it may quickly reverse direction as the large players have filled their positions

.

When a liquidity level is grabbed, many open trade positions are rapidly closed. This happens because retail traders often place their stop losses just above swing highs or below swing lows. The sudden trigger of these stops creates a spike in volume, followed by a shift in momentum.

LIQUIDITY GRAB

There are two types of liquidity grabs: bullish and bearish, and each one targets a different side of the market.

- To spot a bullish liquidity grab, focus on Sell-side Liquidity (SSL) levels. These are usually found below recent lows, where long traders have placed their stop losses. When price sweeps below a low, triggers those stops, and quickly reverses upward, that is a bullish liquidity grab. It often signals that smart money has entered long positions after collecting sell-side liquidity.

- To identify a bearish liquidity grab, look at Buy-side Liquidity (BSL) levels. These are typically above recent highs, where short sellers have placed their stop losses. When price pushes above a high, triggers those stops, and then reverses downward, that is a bearish liquidity grab. It shows smart money may have used the liquidity to open short positions.

XII. IFVG

An Inverse Fair Value Gap (IFVG) is a significant imbalance zone that can signal a potential trend reversal in the market. It is considered a key price area where momentum may shift direction.

An IFVG forms when a previously clean Fair Value Gap (FVG) becomes invalidated, usually by a candle wick or full candle close passing through the gap. This action shows that the imbalance has been filled or rejected, and that price is no longer respecting the original FVG structure.

Traders watch for IFVGs as signs of weakening trend strength. When confirmed with other confluences like volume or liquidity grabs, an IFVG can be used as a reversal zone or a strong resistance or support level.

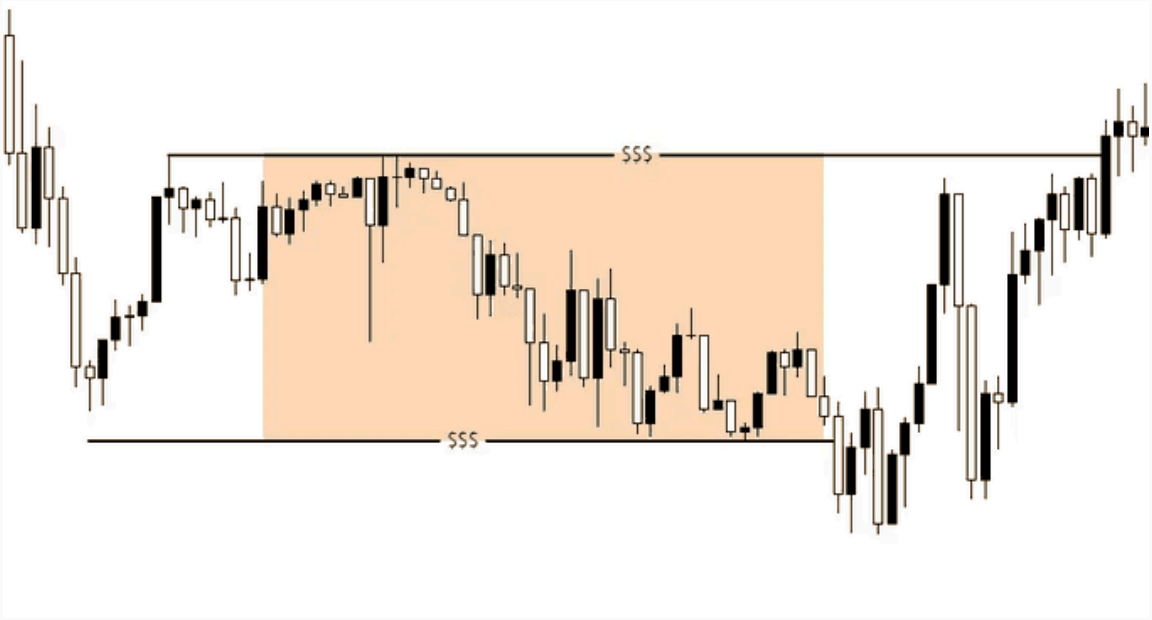

XIII. KILLZONES

Asian Trading Session (Tokyo Session)

The Asian session is led by the Tokyo market, running from 00:00 AM to 09:00 AM GMT.

It has lower volatility compared to the London and New York sessions due to reduced liquidity and smaller price movements. Pairs like JPY, AUD, and NZD are more active during this time.

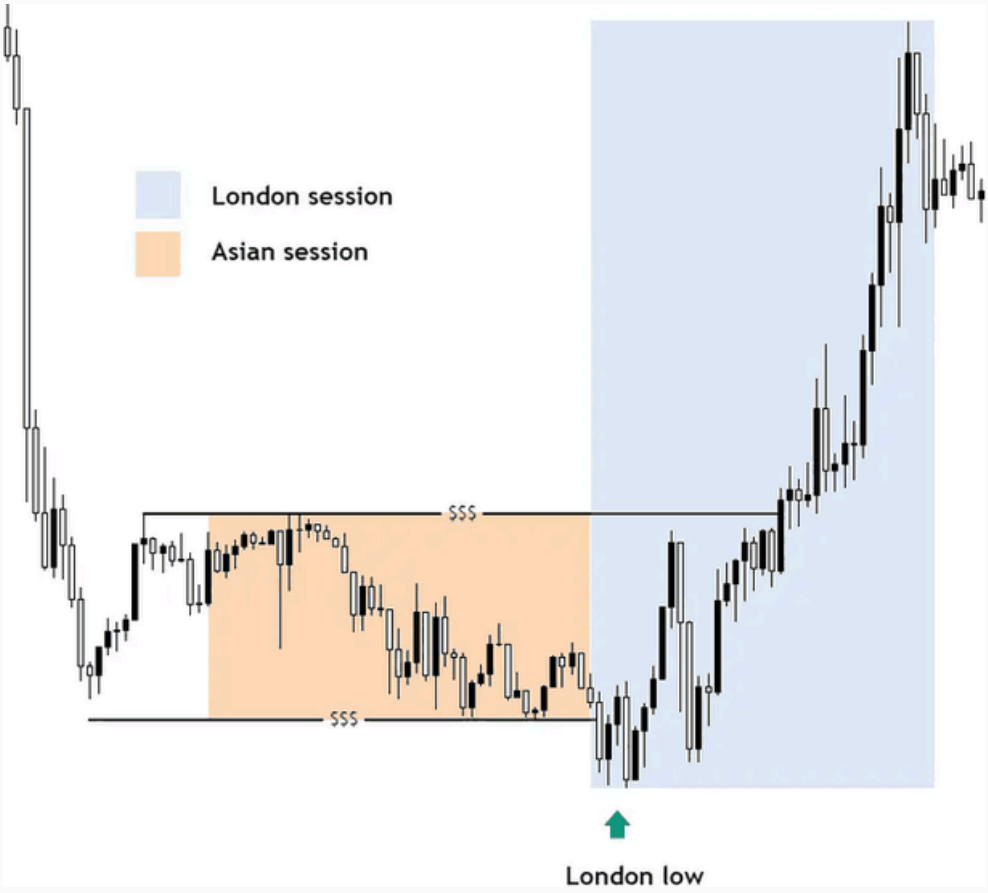

KILLZONES

London Trading Session

The London session runs from 8:00 AM to 5:00 PM GMT.

It has high volatility and liquidity due to strong participation from banks, hedge funds, and institutional traders. This session often sets the day's major trends.

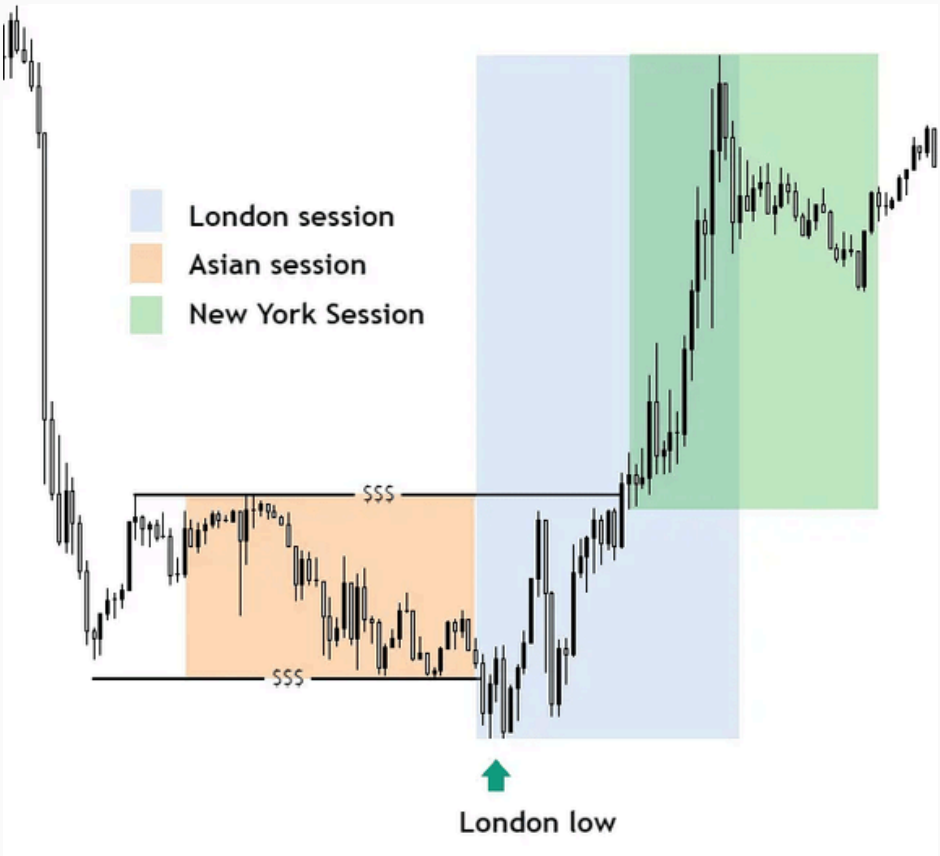

KILLZONES

New York Trading Session

The New York session runs from 13:00 to 22:00 GMT.

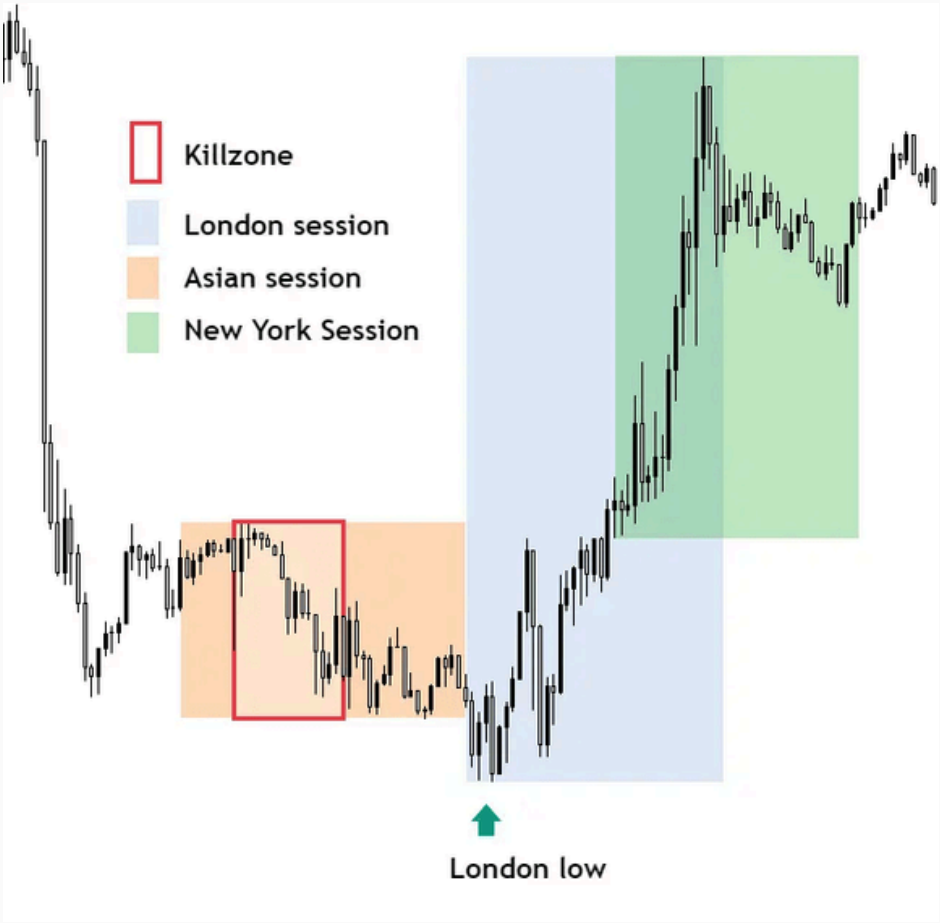

It is the second-most liquid session, and its overlap with London creates the most active period of the trading day.

KILLZONES

The **Killzone** refers to the period of peak volatility during the Asian session, typically between 11:00 PM and 3:00 AM GMT.

This volatility mainly comes from the Tokyo session opening, which brings in increased market activity and volume.

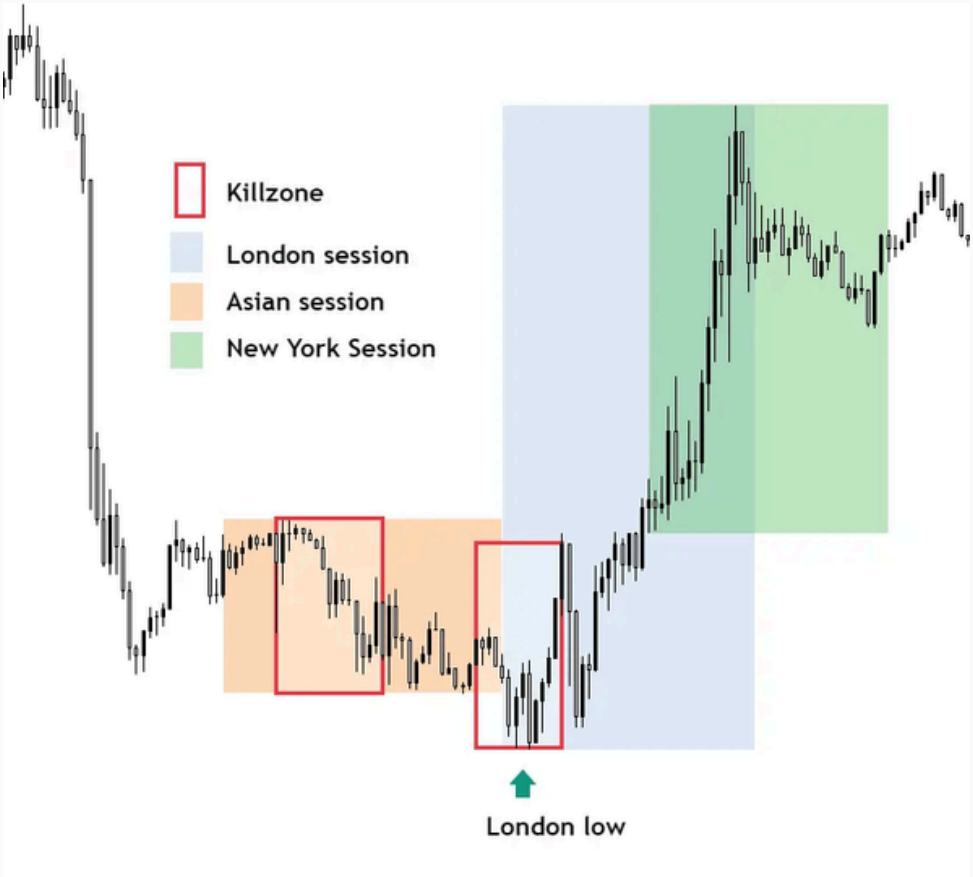

KILLZONES

The London Killzone takes place from 7:00 AM to 9:00 AM GMT, just before and after the London open.

During this time, liquidity is often swept, and the high or low of the day is frequently set.

This pattern tends to repeat consistently across many trading days.

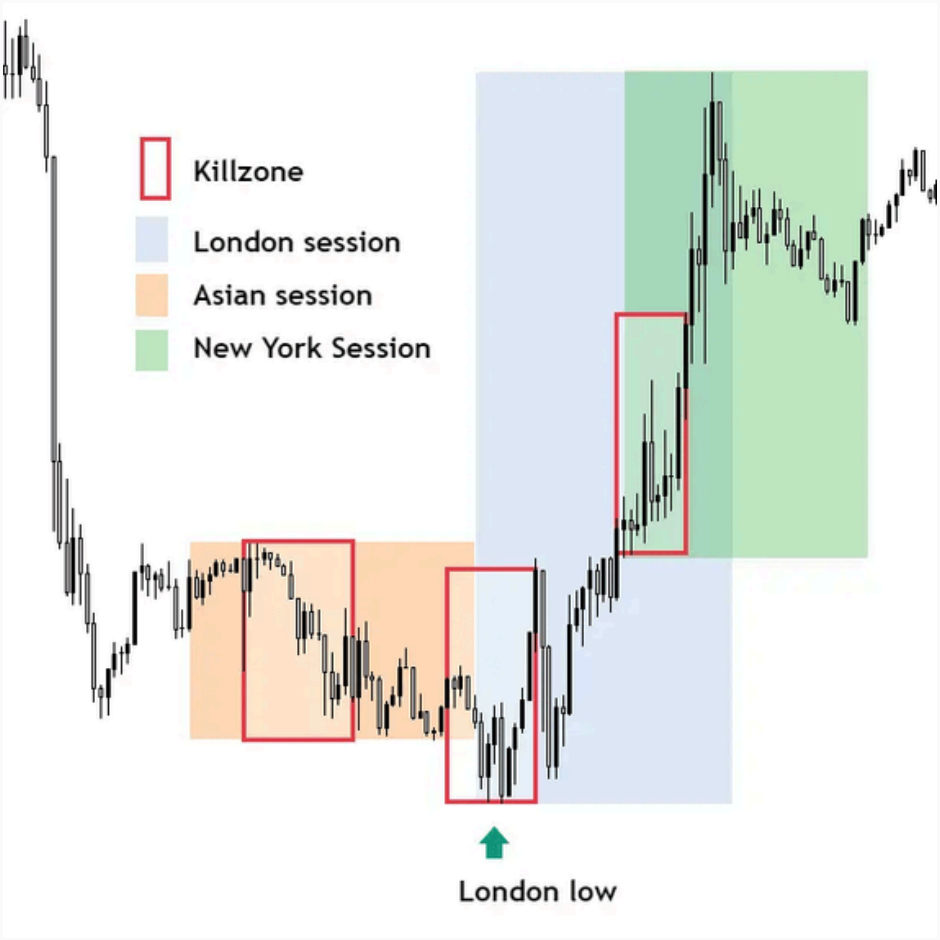

KILLZONES

New York Killzone

The New York Killzone runs from 12:00 PM to 2:00 PM GMT, just before the US session opens.

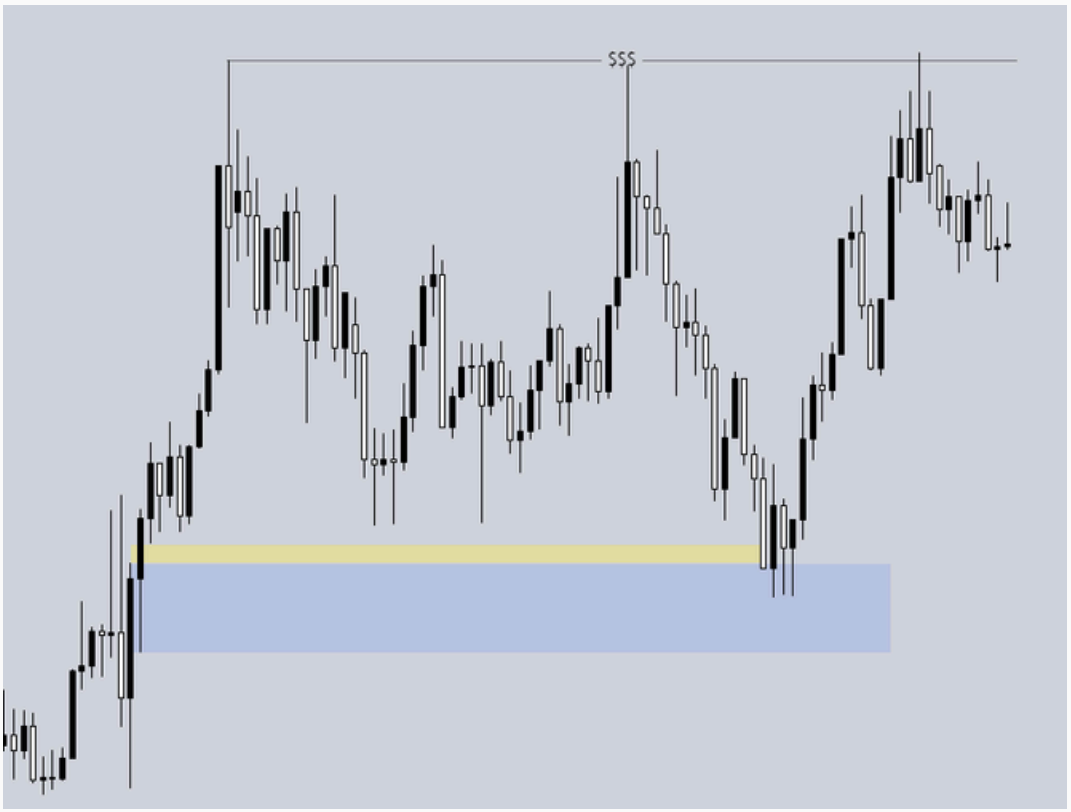

It starts early as investors anticipate market direction, leading to increased volatility and potential liquidity grabs before the official open.

XIV. POI

A POI is a key price level or zone that traders watch for potential reversals, breakouts, or reactions.

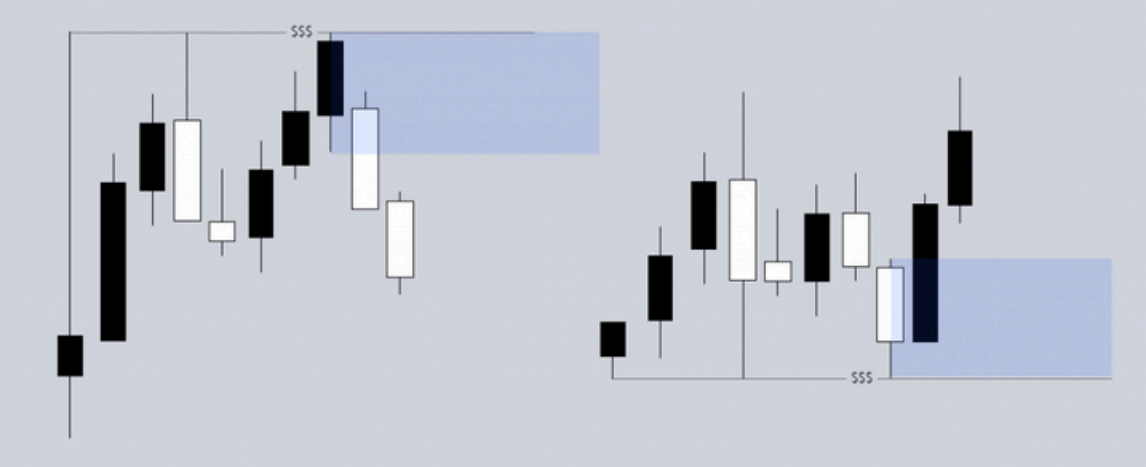

It is usually based on historical support or resistance, market structure, or areas with high liquidity.

POI

In these charts, key supply zones (shaded areas) align with potential Points of Interest (POIs).

Wicks at highs and lows often reveal liquidity pockets, where stop losses are clustered. Price tends to retest these zones, making them ideal for traders watching for reversals or breakouts.

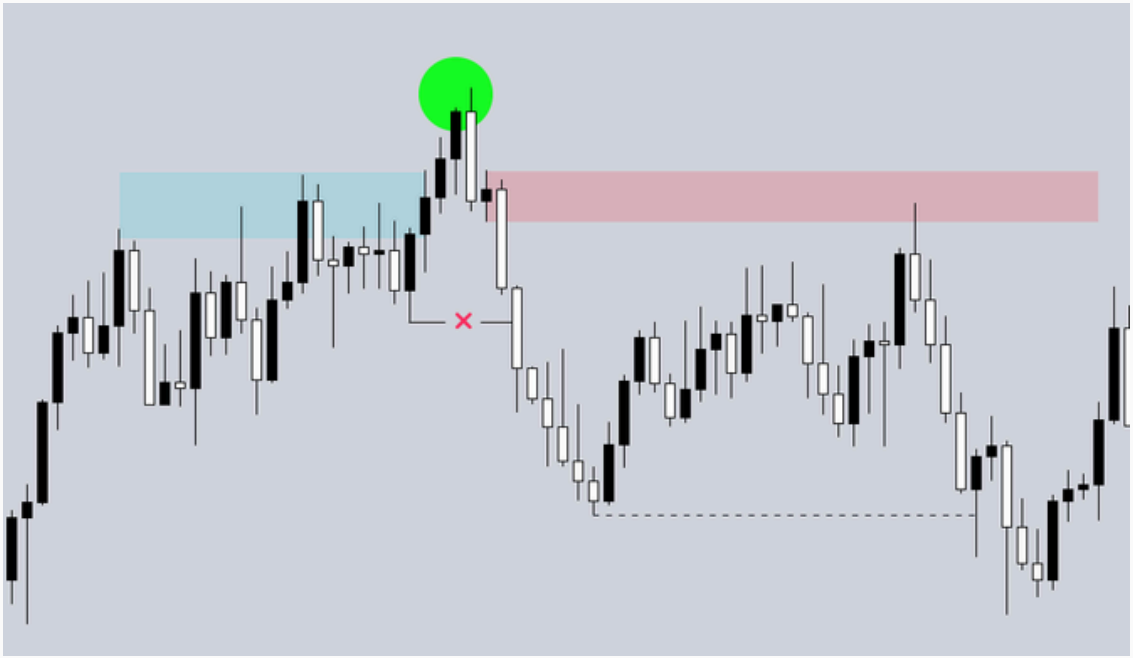

POI

Points of Interest (POIs) mark key price levels on a chart where traders have historically shown strong reactions. These areas often line up with important support or resistance zones, supply and demand levels, or liquidity pools.

POIs are used to anticipate reversals or breakouts, helping traders identify high-probability setups. They serve as guides for planning entries and exits, setting stop losses, and improving risk management.

By focusing on these zones, traders can better align their decisions with market behavior and the actions of larger participants.

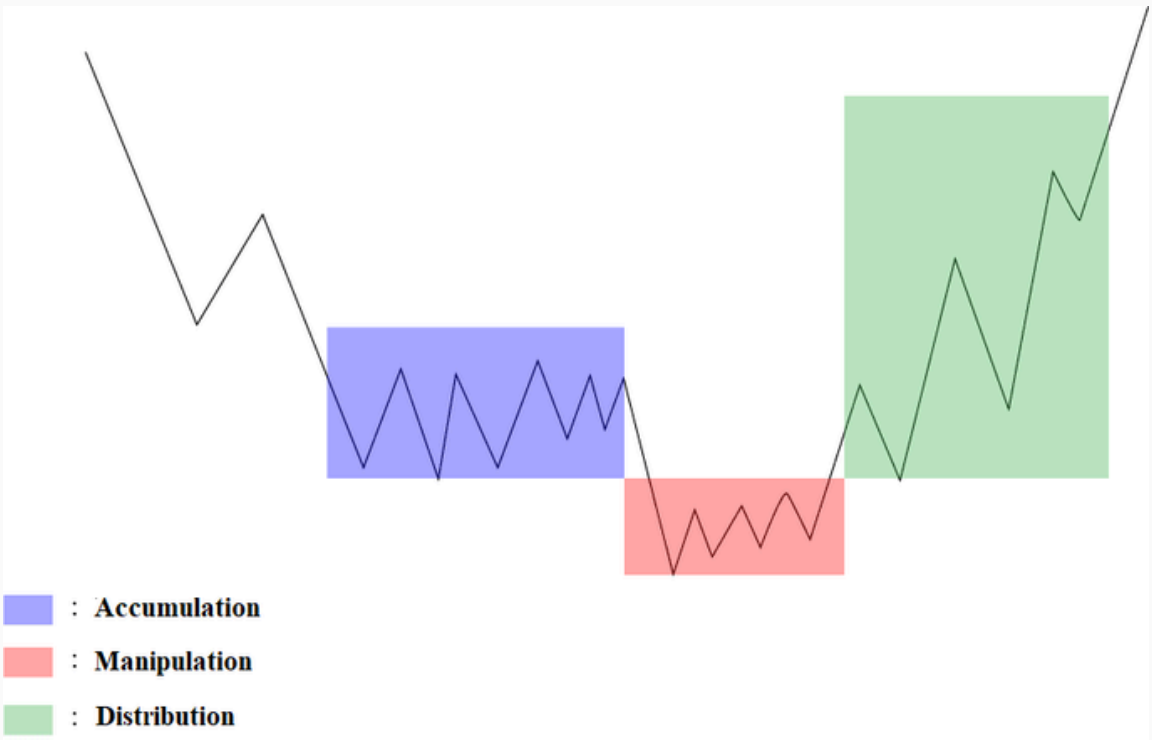

XV. POWER OF THREE (PO3)

The Power of Three is a price action concept divided into three key phases: Accumulation, Manipulation, and Distribution.

- Accumulation is when the market moves sideways, building positions and drawing in retail traders.
- Manipulation occurs when price briefly breaks out of the range, triggering stop losses or fake moves.
- Distribution is the final phase where the real move happens in the intended direction.

This setup helps traders build a market narrative and spot key institutional levels, allowing for more informed trade entries and exits.

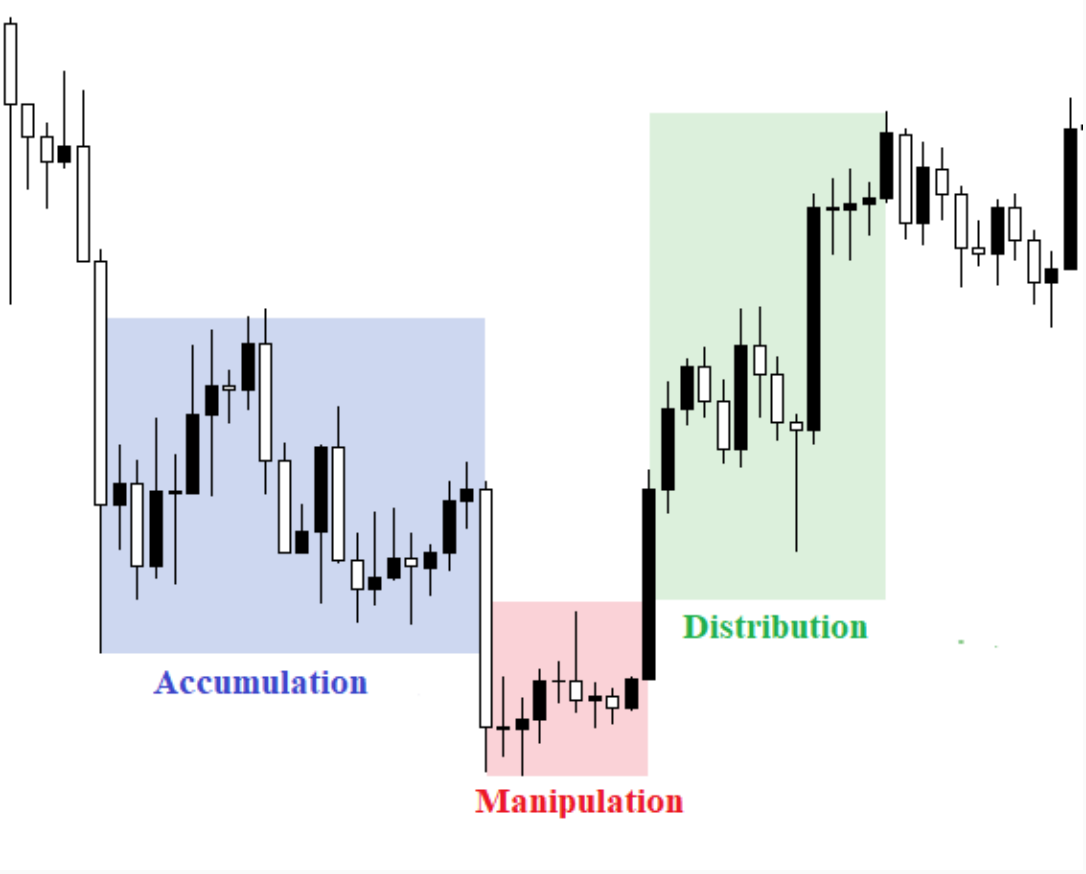

POWER OF THREE (PO3)

1. **Accumulation**
This is the phase where smart money quietly builds positions over time. Price usually moves sideways in a tight range as institutions buy without causing a noticeable price increase. Retail traders often overlook this phase, seeing it as market indecision.

2. **Manipulation**
Once positions are built, institutions push price sharply in one direction to trigger stop losses or breakout orders. This creates a false move that lures retail traders in the wrong direction, providing the liquidity needed for large players to fill their orders.

3. **Distribution**
In this final phase, smart money begins to sell their holdings at higher prices to retail traders who are late to the move. Price often appears strong before reversing, leaving retail trapped while institutions exit profitably.

XVI. LIQUIDATION LEVELS

Liquidation Levels are estimated price points where forced liquidations of leveraged positions may occur. These levels highlight where traders using margin are likely to get stopped out if the market moves against them.

By analyzing these zones, traders can:

- Identify potential support and resistance levels
- Spot where stop losses (SLs) are clustered
- Gauge overall market sentiment and positioning

LIQUIDATION LEVELS

These liquidation levels are formed around clusters of price points where highly leveraged traders have entered long or short positions. These traders are more vulnerable to being liquidated when price moves slightly against them.

High leverage is typically identified as 100x, 50x, or 25x positions. These levels act as liquidity targets, since even small price moves can trigger mass liquidations, creating sharp volatility and rapid market reactions. Understanding where these clusters are located helps traders anticipate key price zones and potential stop hunts.

LIQUIDATION LEVELS

A cluster of liquidation levels aligning with the trend signals strong market conviction. When liquidation zones stack in the same direction as the current move, it indicates that many traders are heavily positioned with the trend.

This reinforces the trend's momentum, as it suggests that smart money may continue pushing price in that direction to liquidate overleveraged positions and maintain control of the move.

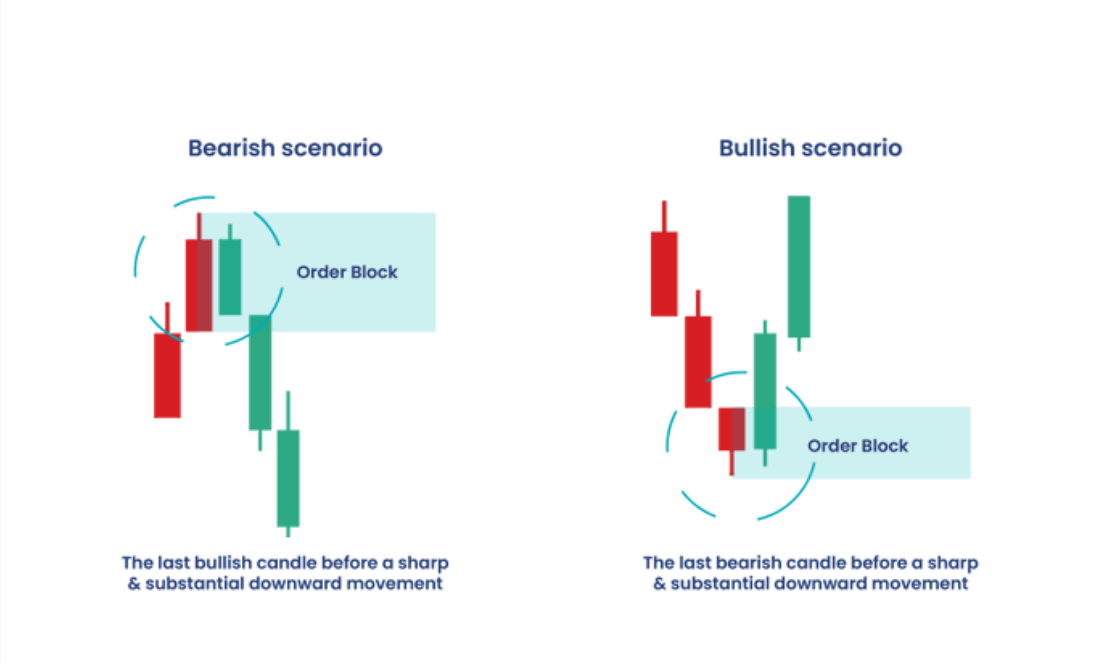

XVII. ORDER BLOCKS

Order Blocks are key zones on the chart where a large number of limit orders are placed by institutional traders. These areas often act as strong support or resistance and can lead to sharp price reactions.

- A **Bullish** Order Block shows a concentration of limit buy orders, typically found before an upward move. Price may return to this zone, react, and continue rising.

- A **Bearish** Order Block contains many limit sell orders, usually formed before a downward move. When price revisits this area, it often faces resistance and reverses lower.

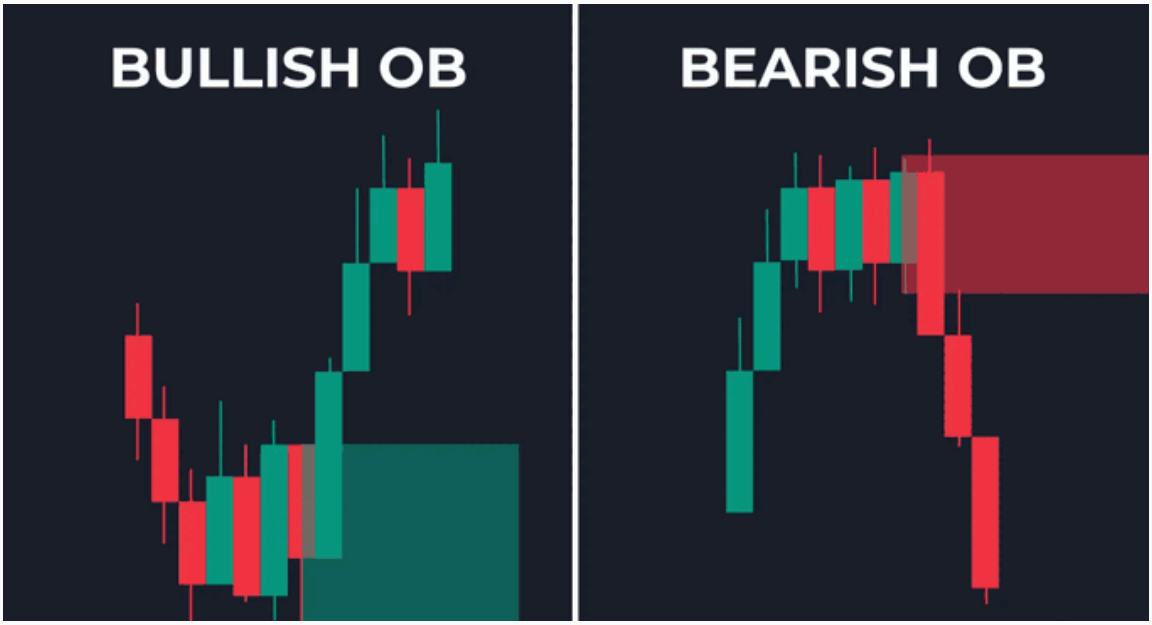

ORDER BLOCKS

The most common way to spot order blocks is by recognizing specific price patterns and market behavior.

To identify a valid order block, look for the following:

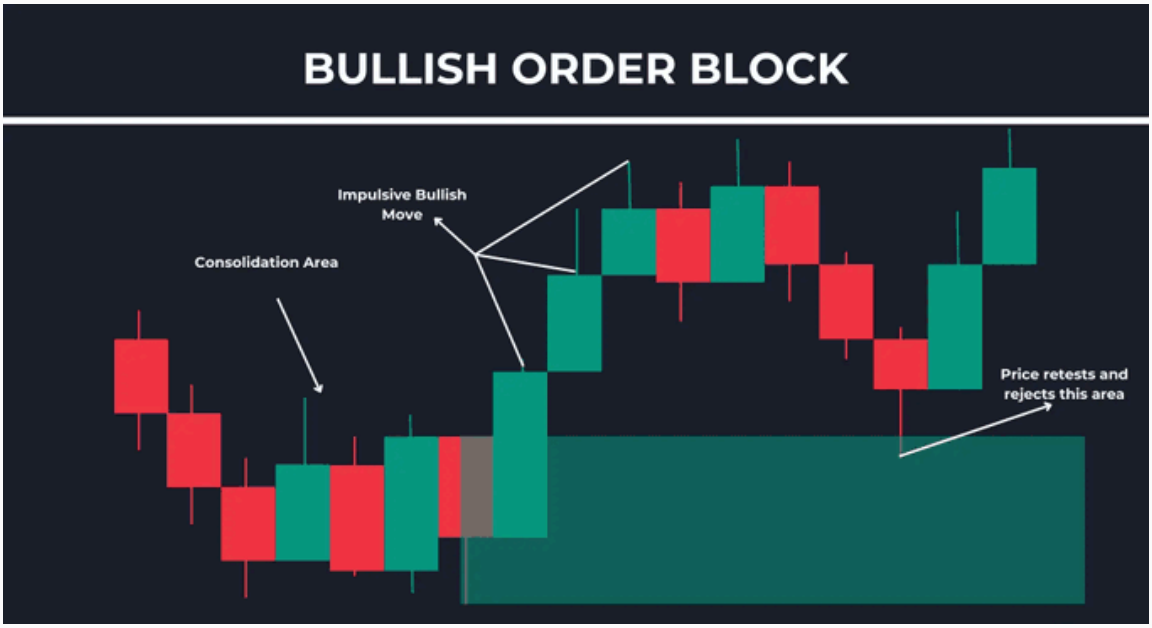

- Liquidity sweeps or takeouts of recent highs or lows
- Imbalances or inefficiencies in price, where one side of the market clearly dominates
- A strong impulsive move away from the zone, showing that large orders were placed there

ORDER BLOCKS

To spot a bullish order block, look for an area of consolidation or sideways movement on your chart that is followed by a strong bullish move. This indicates that buy orders were likely stacked in that zone.

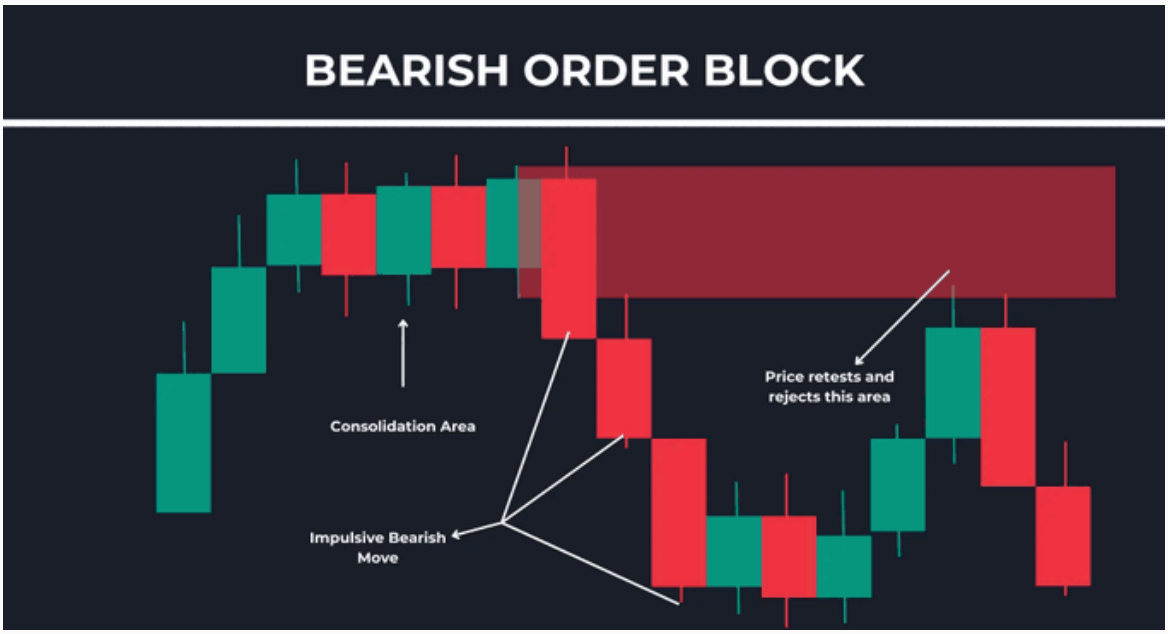

Identify the last bearish candle before the bullish impulse. Then, draw your zone from the low to the high of that candle. This forms the bullish order block, which price may return to before continuing upward.

ORDER BLOCKS

To spot a bearish order block, look for an area of consolidation or range-bound movement on the chart that is followed by a strong bearish move. This suggests that large sell orders were placed in that zone.

Find the last bullish candle before the sharp drop. Draw your zone from the high to the low of that candle. This becomes the bearish order block, where price may retrace before continuing lower.

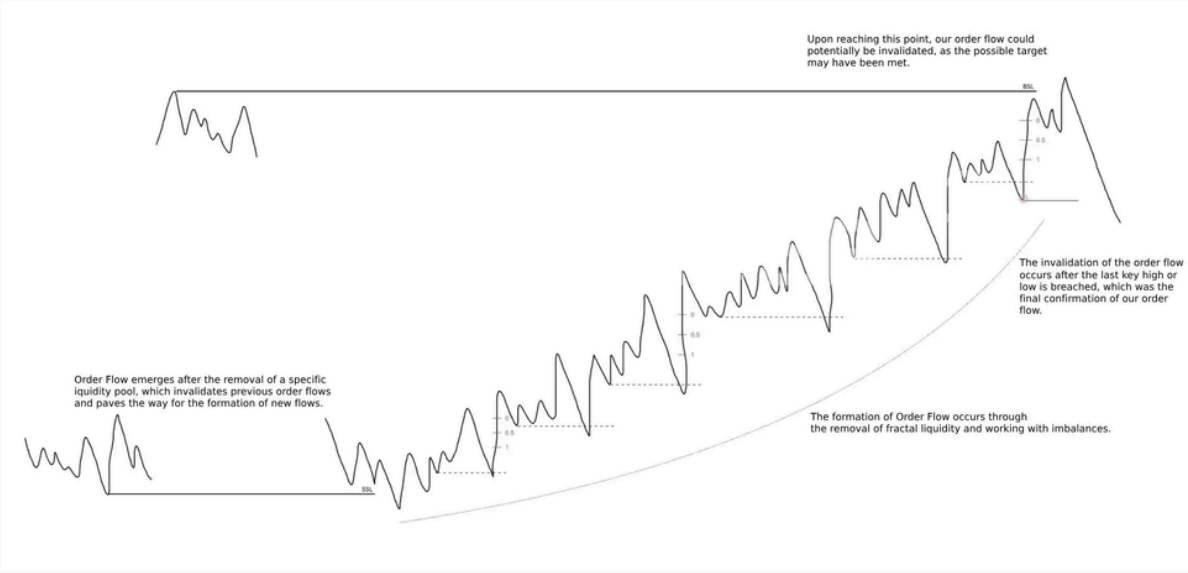

XVIII. ORDER FLOW

Order Flow is the structural movement of price as it reacts to and absorbs liquidity in the market. It helps traders anticipate changes in price by observing how buy and sell orders are placed, filled, or pulled across different levels.

By watching the constant flow of orders of various sizes, you can better understand where liquidity is building, how the market is reacting, and where price is likely to move next.

Order Flow is created with a specific objective, usually to collect liquidity or drive price toward a key level. It always has a clear point of invalidation, which helps traders define risk.

XIX. IMBALANCES

An imbalance occurs when there is an uneven exchange between buyers and sellers. It represents a strong push in one direction, showing that one side of the market is clearly in control.

A bullish imbalance forms when there are more aggressive buyers, while a bearish imbalance shows that sellers dominate.

Imbalances are often seen during impulsive moves where price leaves a gap between candles. This usually appears as full-bodied candles with little to no wick overlap, creating zones the market may revisit later to fill the inefficiency.

IMBALANCES

An imbalance occurs when there is an uneven exchange between buyers and sellers. It represents a strong push in one direction, showing that one side of the market is clearly in control.

A bullish imbalance forms when there are more aggressive buyers, while a bearish imbalance shows that sellers dominate.

Imbalances are often seen during impulsive moves where price leaves a gap between candles. This usually appears as full-bodied candles with little to no wick overlap, creating zones the market may revisit later to fill the inefficiency.

XX. LIQUIDITY VOIDS

Exhaustion liquidity voids occur at the end of a trend when the market loses momentum. These gaps form when price makes one final push without enough volume or strength to continue.

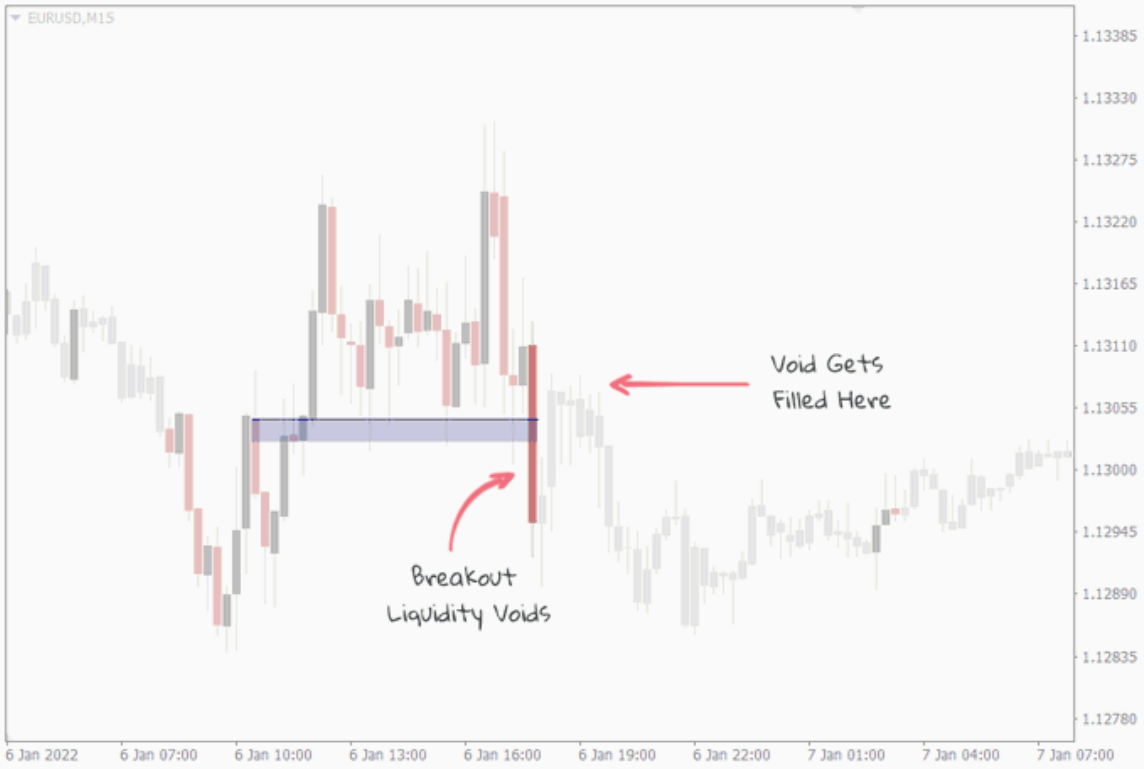

When this happens, the market often releases a final imbalance or gap. This is usually the last move before a reversal, signaling that institutional interest has faded and a shift in direction is likely.

LIQUIDITY VOIDS

Breakout liquidity voids occur when price breaks through a support or resistance level, or clears a key liquidity zone. These gaps are created by a sudden surge in volume and imbalance between buyers and sellers.

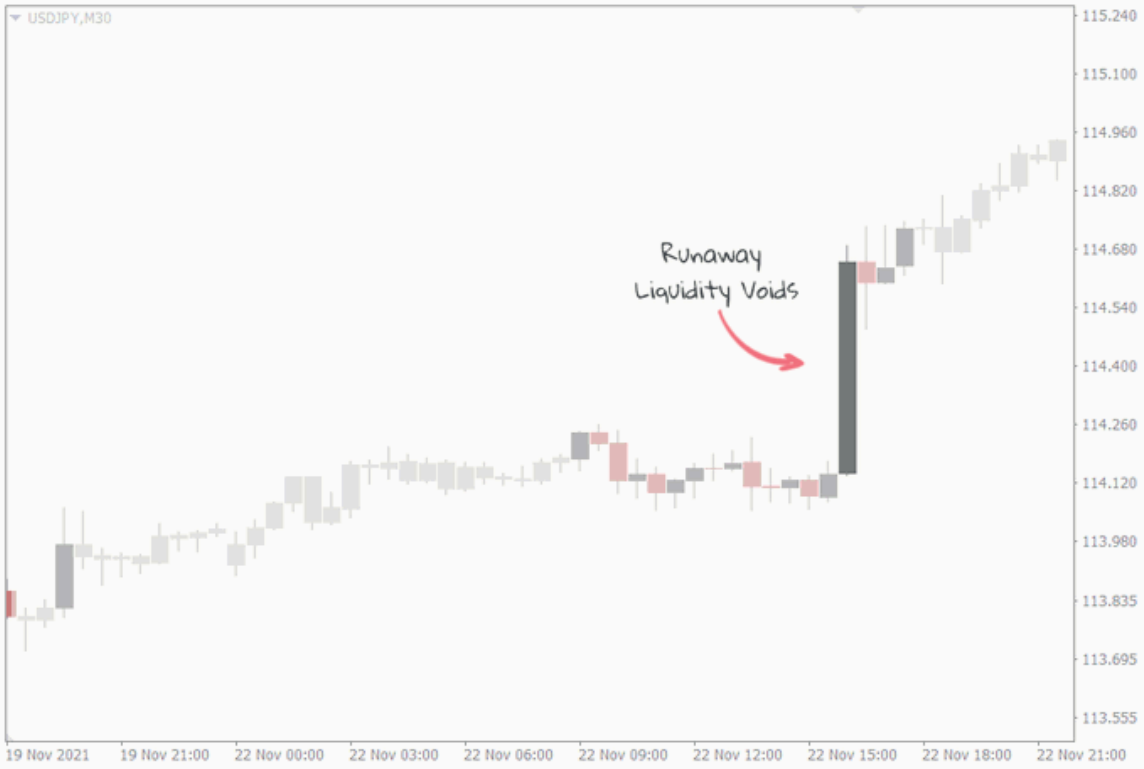

They often signal the start of a new trend, as institutions enter aggressively and drive price away from the breakout zone. These voids can act as strong confirmation for trend continuation.

LIQUIDITY VOIDS

Runaway liquidity voids are also called continuation voids because of where they form on the chart. They appear within an already established trend, often as price moves with strong momentum.

These voids occur in the direction of the trend, showing that the market is efficiently moving with little resistance. They confirm trend strength and often lead to further continuation without deep pullbacks.

LIQUIDITY VOIDS

These liquidity zones or pools often appear as support and resistance levels on the chart.

To identify potential reversal points where the market may fill a liquidity void, watch for liquidity zones that form after the void has occurred. These areas can act as magnets, drawing price back to rebalance the inefficiency.

USING INDICATORS FOR BETTER TRADE DECISIONS

I. WHAT ARE INDICATORS?

Indicators are tools used in technical analysis to help traders interpret price data and make informed decisions. They are typically displayed on charts and are based on mathematical calculations derived from price, volume, or open interest.

Indicators can help identify trends, momentum, volatility, and potential reversal points. Some of the most common include Moving Averages, RSI (Relative Strength Index), MACD, and Stochastic Oscillator.

While indicators are helpful for confirmation, they should always be used alongside price action and market structure for stronger analysis.

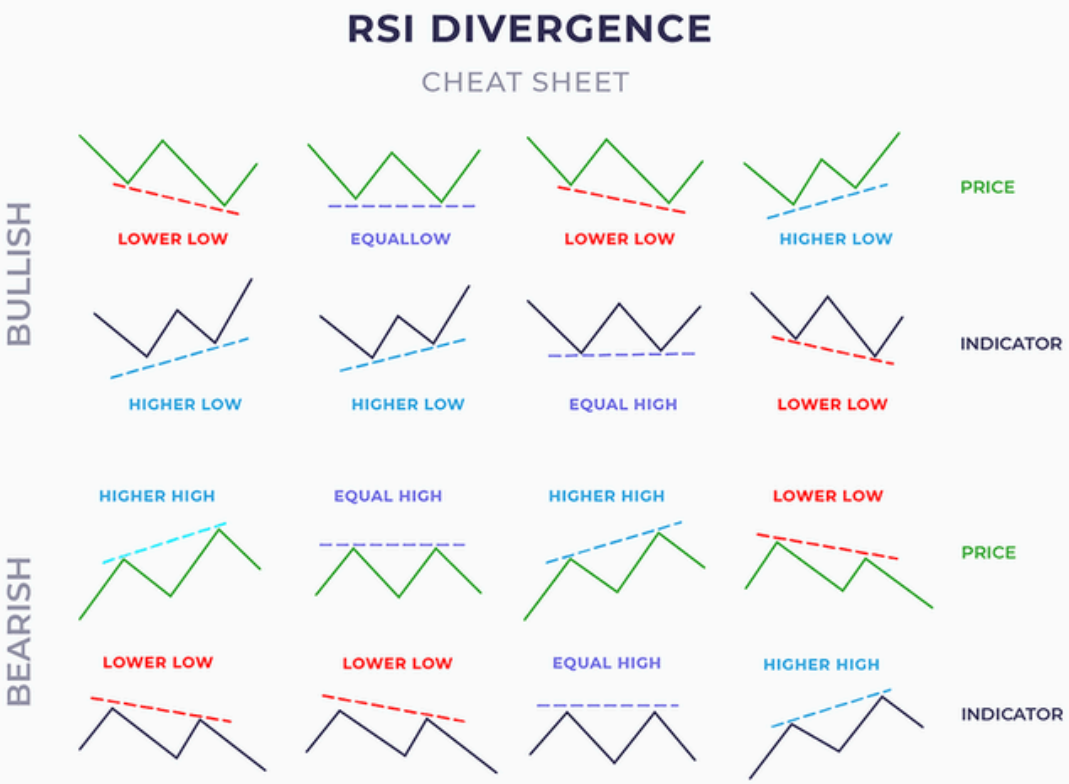

II. RELATIVE STRENGTH INDEX (RSI)

The RSI measures the strength and momentum of price movements, typically on a scale from 0 to 100.

- A Bullish Divergence happens when price makes a lower low, but the RSI forms a higher low. This can signal a potential reversal to the upside.

- A Bearish Divergence occurs when price makes a higher high, but RSI forms a lower high. This suggests weakening momentum and a possible downward reversal.

RSI is especially useful when combined with market structure and support/resistance levels.

RELATIVE STRENGTH INDEX (RSI)

This chart displays a Bearish Divergence on Bitcoin's daily timeframe.

Price forms a higher high around $69,000, while the RSI prints a lower high, indicating that momentum is fading despite the price push.

This type of divergence is a classic warning sign of a potential reversal, which is confirmed by the subsequent drop in price.

RELATIVE STRENGTH INDEX (RSI)

This chart shows a Bullish Divergence on Bitcoin's daily timeframe.

Price forms a lower low near $15,479, while the RSI prints a higher low, signaling that buying momentum is building despite the price drop.

This divergence often signals a potential reversal, confirmed by the strong rally that follows shortly after.

RELATIVE STRENGTH INDEX (RSI)

If the RSI is above 50, it indicates that the average gains are greater than the average losses over the selected period, showing bullish momentum.

When the 200-period RSI stays above 50, it often suggests a long-term uptrend, and traders may focus on buying opportunities that align with the overall direction of the market.

RELATIVE STRENGTH INDEX (RSI)

This chart shows the RSI below 30, signaling an oversold condition in the market.

When RSI falls under this level, it suggests that the asset may be undervalued and due for a bounce.

Traders often use this signal to anticipate potential buying opportunities and a possible price recovery.

III. MACD

A bullish signal occurs when the MACD line crosses above the signal line or the zero line. This crossover suggests a shift in momentum to the upside.

At the same time, the histogram begins to shrink in negativity, showing that bearish pressure is weakening.

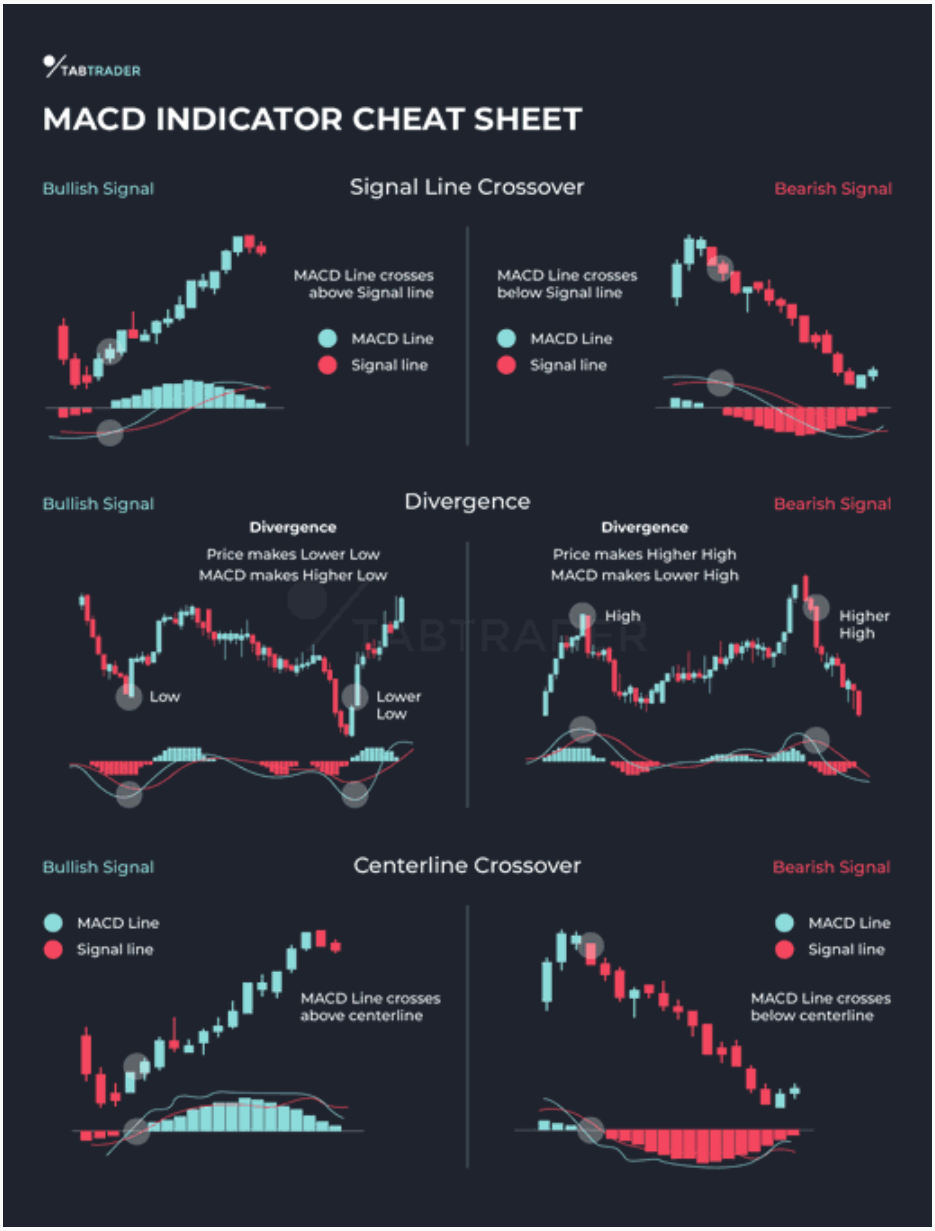

Traders also watch for regular or hidden bullish divergences, which can confirm potential upward momentum or trend continuation.

MACD

In this MACD cheat sheet, you'll find key components that help identify trend shifts and momentum changes:

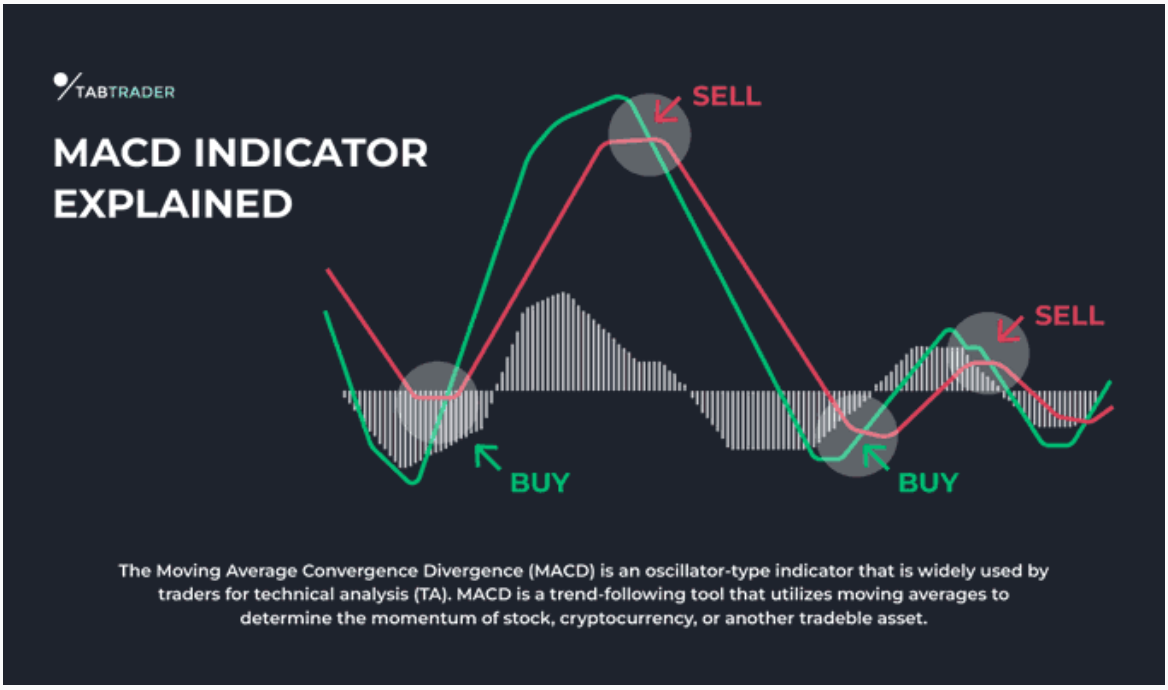

- Signal Line Crossover – When the MACD line crosses above or below the signal line, signaling potential entries or exits.
- Divergence – Bullish or bearish divergences between price and MACD, often indicating upcoming reversals.
- Centerline Crossover – When the MACD line crosses the zero line, confirming bullish or bearish momentum.

MACD

When the MACD line crosses above the Signal line from below, it indicates a bullish trend and potential upward momentum.

When the MACD line crosses below the Signal line from above, it signals a bearish trend and possible downward pressure.

IV. RSI + MACD COMBINATION

The MACD and RSI indicators work well together because they both aim to detect the early stages of bullish or bearish trends.

While the MACD focuses on momentum shifts and trend direction through moving averages, the RSI measures overbought or oversold conditions and can signal potential reversals.

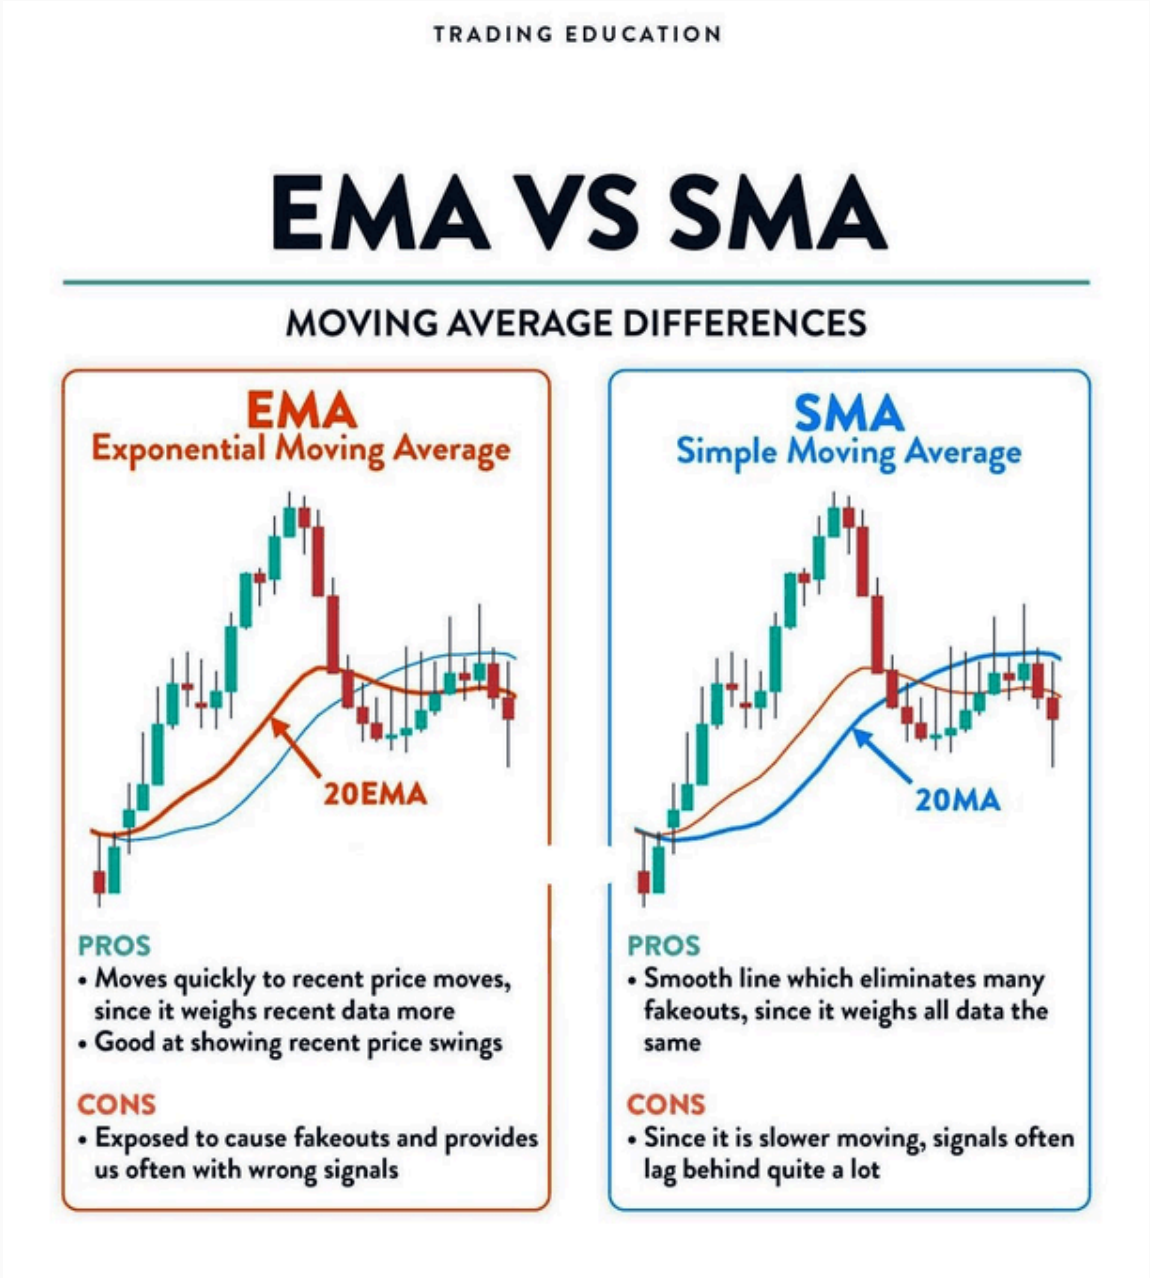

Using only one indicator might lead to false signals, but combining both helps confirm entries, filter out noise, and strengthen trading decisions.

For example, a bullish RSI divergence confirmed by a MACD crossover provides a more reliable signal to enter a long position.

V. MOVING AVERAGES

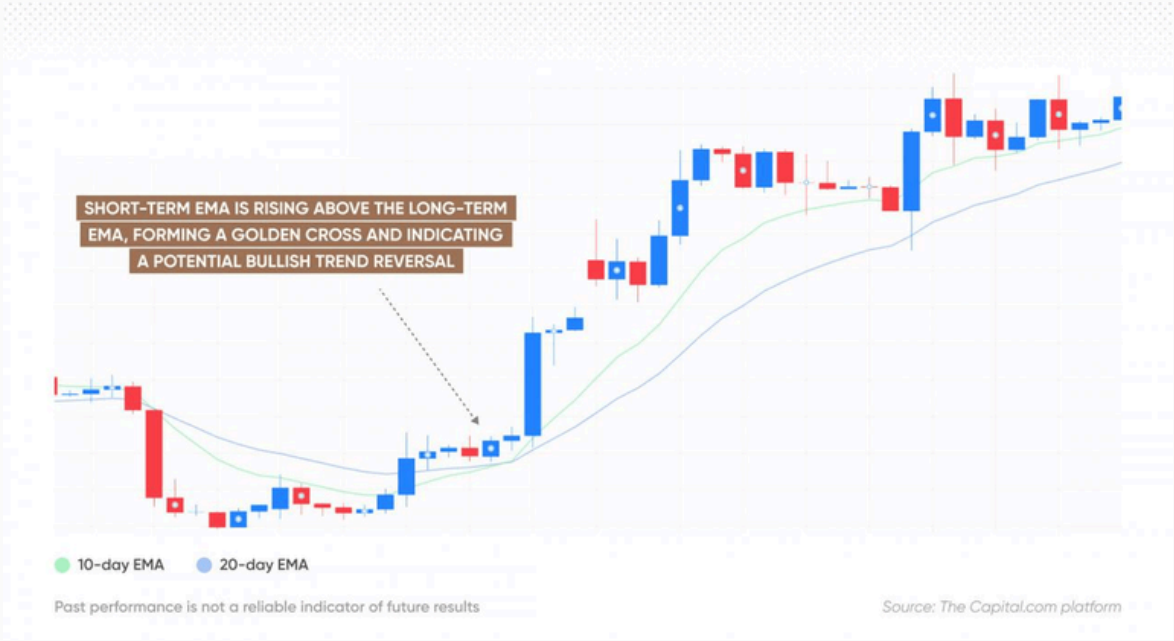

1. EMA (Exponential Moving Average): Gives more weight to recent price movements, making it more responsive and ideal for short-term trading and quick trend shifts.
2. SMA (Simple Moving Average): Gives equal weight to all data points, making it better suited for long-term analysis and identifying overall market direction.

MOVING AVERAGES

The EMA crossover strategy uses two or more Exponential Moving Averages of different periods to spot trend shifts and trading signals.

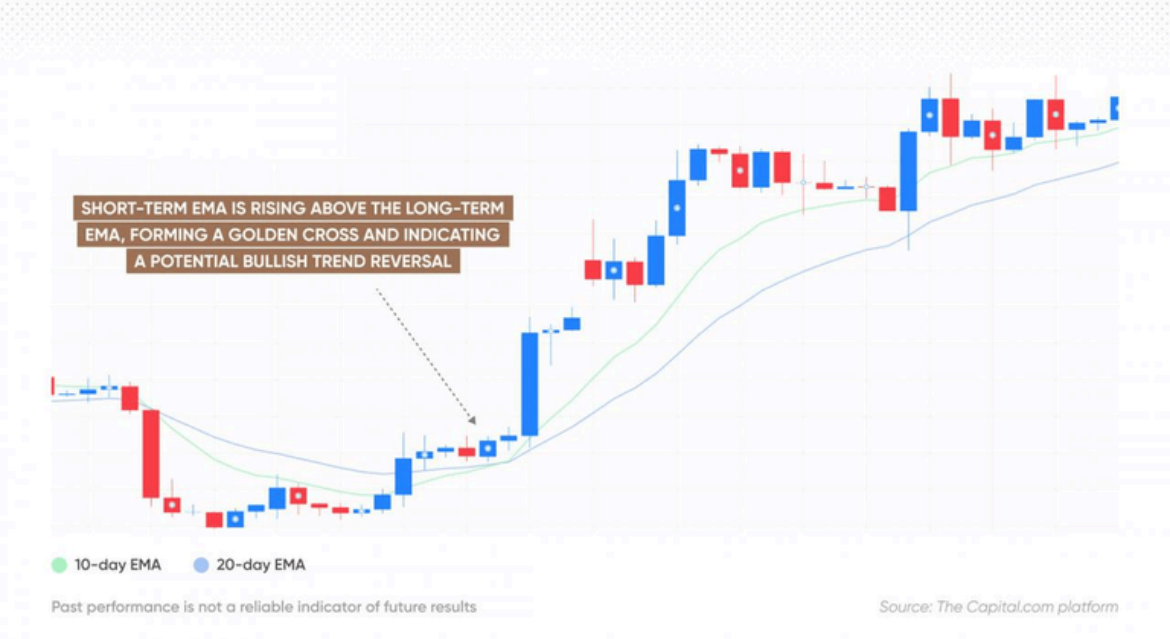

When a shorter-period EMA (like the 9 EMA) crosses above a longer-period EMA (like the 21 EMA), it generates a bullish signal, suggesting upward momentum and a possible entry point.

MOVING AVERAGES

The EMA crossover strategy uses two or more Exponential Moving Averages of different periods to spot trend shifts and trading signals.

When a shorter-period EMA (like the 9 EMA) crosses above a longer-period EMA (like the 21 EMA), it generates a bullish signal, suggesting upward momentum and a possible entry point.

MOVING AVERAGES

To identify the trend, watch the slope and position of the EMA in relation to price.

If the EMA is angled upward and positioned below the price, it typically signals bullish momentum and continued upward pressure.

VI. BOLLINGER BANDS

Bollinger Bands are a widely used technical indicator that helps traders assess price volatility and spot potential trend reversals.

They consist of three lines plotted on a chart:

- The Upper Band (shows overbought levels)
- The Middle Band (usually a 20-period moving average)
- The Lower Band (shows oversold levels)

When price touches or moves beyond the upper or lower bands, it can signal a reversal or a strong continuation, depending on volume and market context.

BOLLINGER BANDS

Bollinger Bands adjust based on price volatility. The bands expand when the market is highly volatile or trending strongly, capturing wider price swings.

During sideways movement or periods of low momentum, the bands contract, reflecting tighter price action and consolidation.

BOLLINGER BANDS

Bollinger Band contraction happens when the bands tighten, indicating low volatility and a period of consolidation.

This phase often precedes a breakout, as the market builds up momentum.

To anticipate the direction of the breakout, traders often rely on volume spikes or supporting indicators like RSI or MACD.

BOLLINGER BANDS

Bollinger Band expansion occurs when the bands widen, signaling increased volatility in the market.

Breakouts that happen during expansion are generally more reliable, especially when supported by strong volume, confirming the start of a new trend.

BOLLINGER BANDS

When price breaks above the upper band or below the lower band but then quickly reverses, it's considered a fakeout.

The bands widen, suggesting higher volatility, but the lack of follow-through shows the breakout was weak. Always watch for low volume or lack of confirmation, as these often signal the move is unsustainable.

VII. VWAP

VWAP is a technical analysis indicator that reflects the average price an asset has traded at throughout the day, weighted by volume. It gives more importance to price levels with higher trading activity.

It is calculated by dividing the total dollar value traded (price times volume) by the total volume traded over a specific time frame.

VWAP is widely used by institutional traders, scalpers, and intraday traders as a benchmark to evaluate whether the current price is overvalued or undervalued compared to the day's trading activity.

- If the price is above VWAP, it may signal bullish sentiment.
- If the price is below VWAP, it often indicates bearish sentiment.

VWAP can also act as dynamic support or resistance, helping traders make more informed entry and exit decisions during the trading day.

VIII. ICHIMOKU CLOUD

The Ichimoku Cloud is a technical indicator that shows trend direction, support and resistance, and momentum.

It's made up of five lines that form a "cloud," which helps traders identify bullish or bearish zones.

- Above the cloud = Bullish
- Below the cloud = Bearish
- Inside the cloud = Consolidation

It's useful for spotting trend strength and future price zones.

IX. VOLUME PROFILE

The Volume Profile is a trading indicator that shows how much volume was traded at each price level over a specific time period.

It helps traders spot key levels of interest, such as support and resistance zones, based on where the most buying or selling took place.

The most common type is the Visible Range Volume Profile, which adjusts to the part of the chart currently in view.

VOLUME PROFILE

High Volume Nodes (HVNs) show price levels where large volumes of trading activity occurred, indicating strong interest from buyers and sellers.

Once HVNs are identified, traders should analyze price action around these zones and look for historical support, resistance, or consolidation structures to guide trade decisions.

VOLUME PROFILE

Related structures are historical price levels that the market has previously respected, often acting as support or resistance and triggering strong price reactions.

When marking these areas, it's important to consider both the candle closes and the wicks, as they give clues about liquidity grabs and true rejection zones.

VOLUME PROFILE

Low Volume Nodes (LVNs) mark price levels where there has been relatively little trading activity.

These areas show a lack of liquidity, which often leads to faster price movement through them, since there is less resistance or support holding price in place.

VOLUME PROFILE

After spotting Low Volume Nodes (LVNs), analyze the price action and identify historical structures that align with those zones.

These zones often act as liquidity areas, where price can move quickly once entered.

They are usually based on a combination of wicks and candle closes, helping traders spot potential breakout or rejection points.

VOLUME PROFILE

After spotting Low Volume Nodes (LVNs), analyze the price action and identify historical structures that align with those zones.

These zones often act as liquidity areas, where price can move quickly once entered.

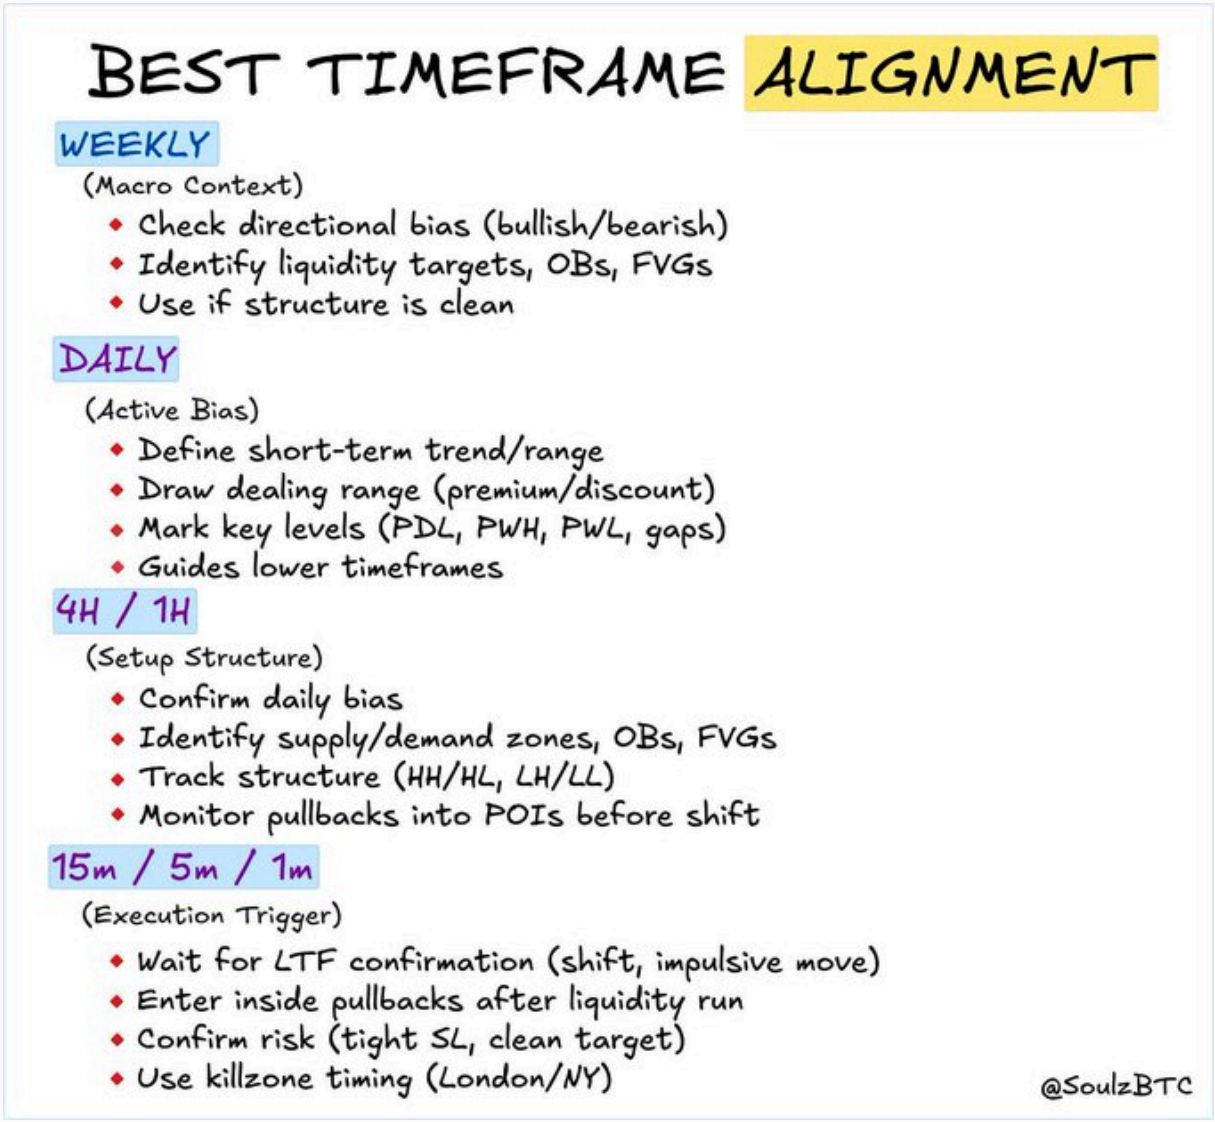

They are usually based on a combination of wicks and candle closes, helping traders spot potential breakout or rejection points.

TRADER'S TOOLKIT: CHEAT SHEETS

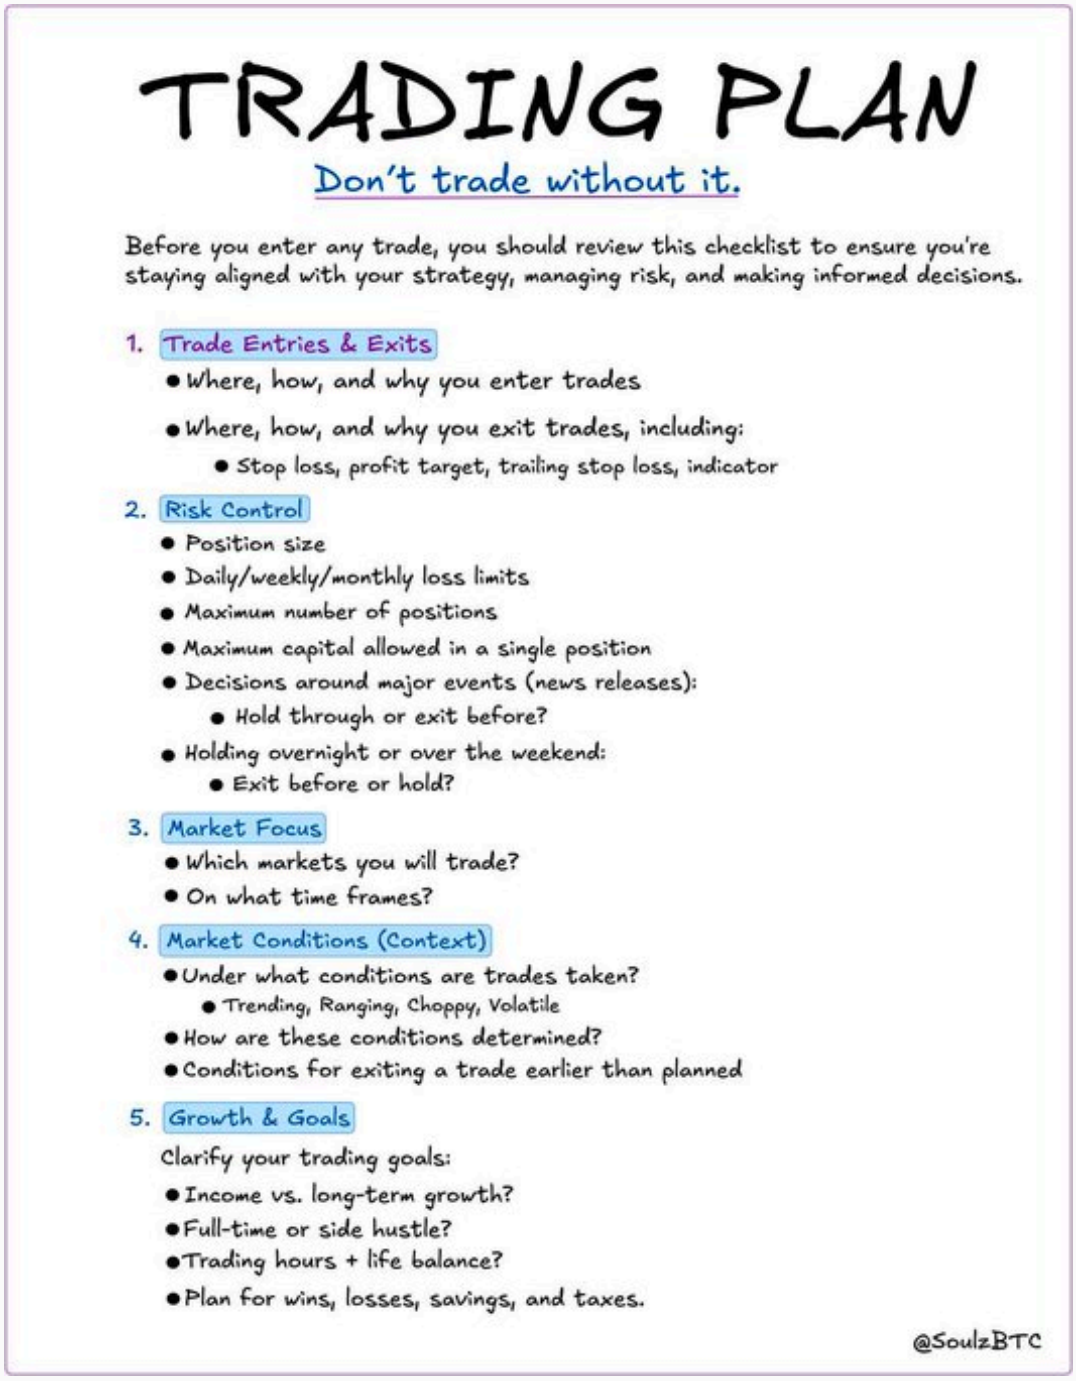

I. BEST TIMEFRAME ALIGNMENTS

Before you take a trade, follow this Timeframe guide:

II. Trading Plan #1

Before taking a trade, follow this guide:

TRADING PLAN

Don't trade without it.

Before you enter any trade, you should review this checklist to ensure you're staying aligned with your strategy, managing risk, and making informed decisions.

1. **Trade Entries & Exits**
   - Where, how, and why you enter trades
   - Where, how, and why you exit trades, including:
     - Stop loss, profit target, trailing stop loss, indicator
2. **Risk Control**
   - Position size
   - Daily/weekly/monthly loss limits
   - Maximum number of positions
   - Maximum capital allowed in a single position
   - Decisions around major events (news releases):
     - Hold through or exit before?
   - Holding overnight or over the weekend:
     - Exit before or hold?
3. **Market Focus**
   - Which markets you will trade?
   - On what time frames?
4. **Market Conditions (Context)**
   - Under what conditions are trades taken?
     - Trending, Ranging, Choppy, Volatile
   - How are these conditions determined?
   - Conditions for exiting a trade earlier than planned
5. **Growth & Goals**

   Clarify your trading goals:
   - Income vs. long-term growth?
   - Full-time or side hustle?
   - Trading hours + life balance?
   - Plan for wins, losses, savings, and taxes.

@SoulzBTC

III. Trading Plan #2

Before taking a trade, follow this guide:

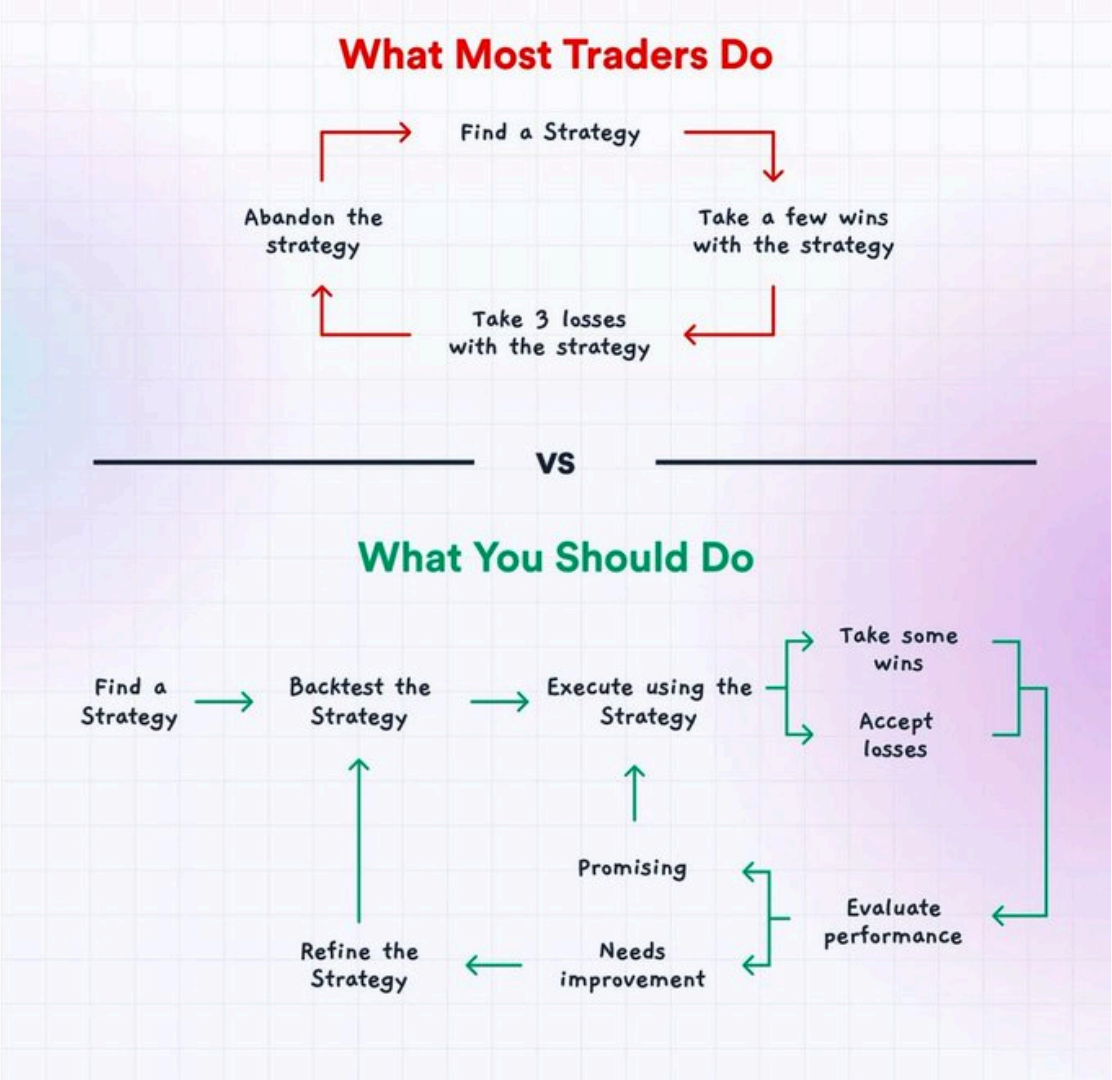

III. Trading Plan #3

Before taking a trade, ask yourself these questions:

IV. Trading Plan #4

Before taking a trade, follow this list:

TRADING LIQUIDITY LIKE SMART MONEY

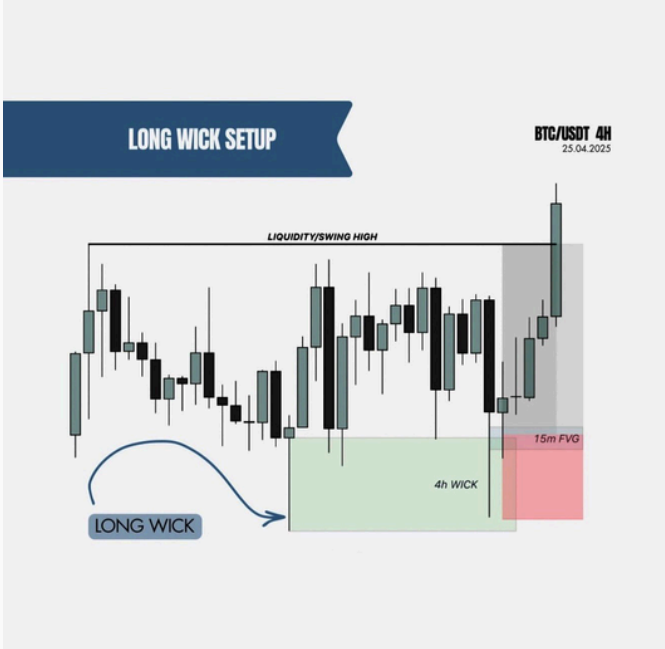

I. LIQUIDITY TRADING STRATEGY #1

1) Identify Liquidity on Higher Time Frame

2) Take the trade after a Liquidity Sweep on the Lower Time Frame

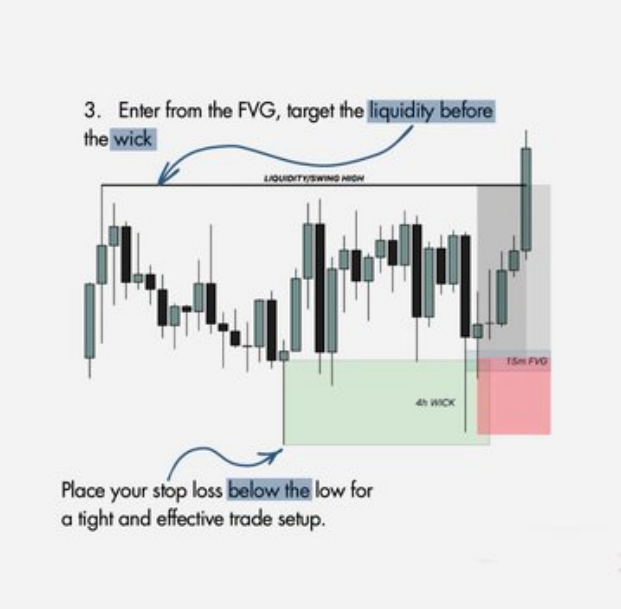

3) Place your Stop Loss below the Swing Low

4) Target the Liquidity Zone

II. LIQUIDITY TRADING STRATEGY #2

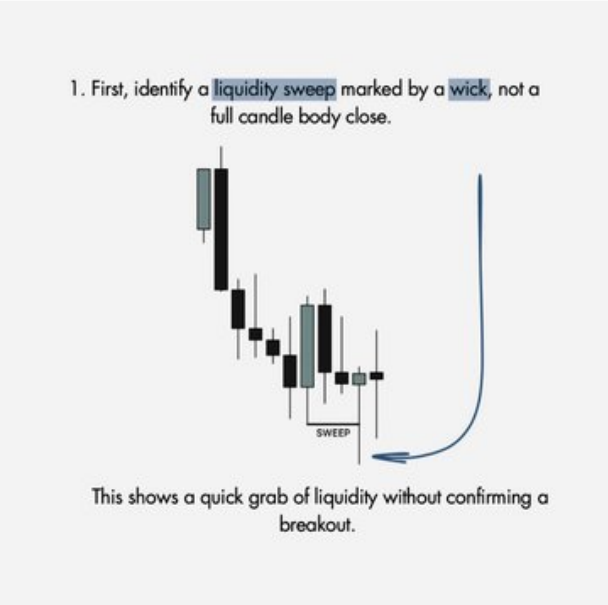

1) Find the Liquidity Sweep. It's a wick that takes out the low

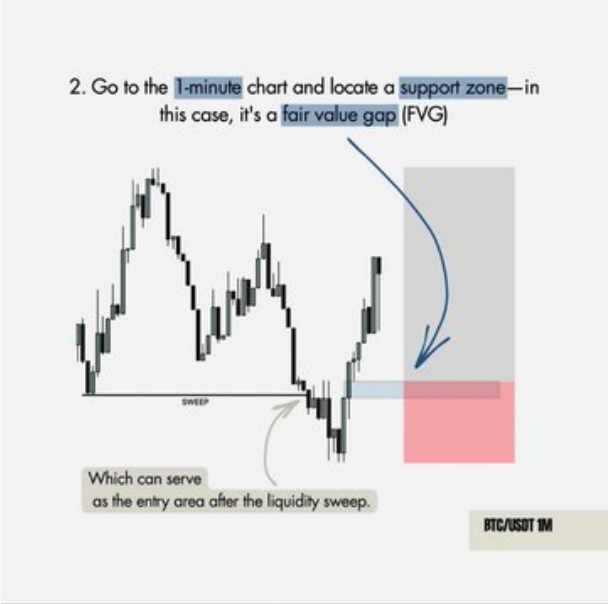

2) Identify the Demand Zone in LTF. Usually it will be a FVG

3) Set your Stop Loss below that Demand Zone.

4) Target the Liquidity Zone

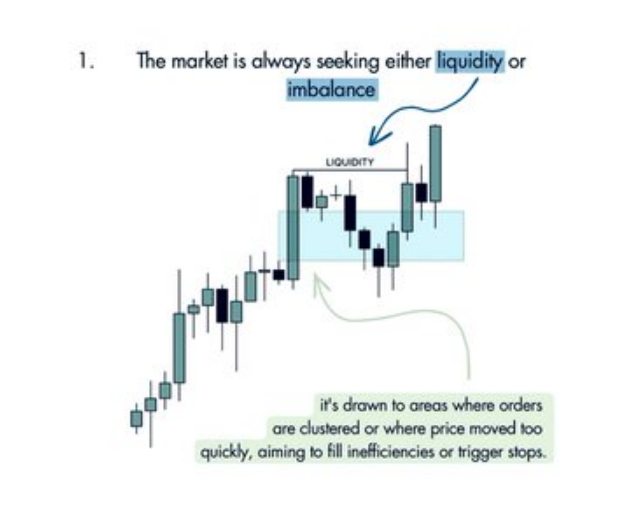

LIQUIDITY TRADING STRATEGY #3

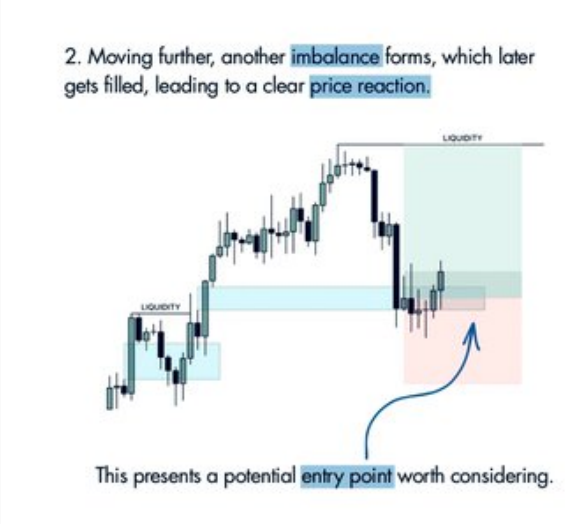

1) Identify Liquidity on Higher Time Frame

2) Take the trade after a Liquidity Sweep on the Lower Time Frame

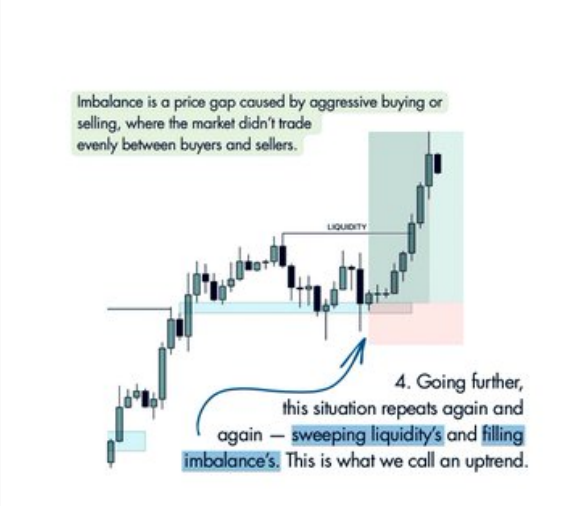

3) Place your Stop Loss below the Swing Low

4) Target the Liquidity Zone

Congratulations on completing this advanced guide.

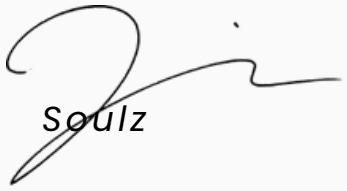

We've explored liquidity zones, advanced price-action tactics, structural pivots, market structure and many many more.

I want to thank each of you for reading, for your comments, and for supporting this content.

Your engagement makes it possible for me to share it to a bigger public and I'm honored to be on this journey with you.

Stay curious, stay humble, and above all, keep practicing what you've learned.

Sincerely,

Soulz
